47.55E Nozzles

71622 Results of the investigation of the motion of particles in a Laval nozzle. S.F.Ignatov, D.S.Mikhatulin, I.V.Chirkov.
Fluid Dyn. (USA), vol.17, no.4, p.626-31 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.163-8 (July-Aug. 1982). [received: April 1983]
The calculation of the two-phase flow in a nozzle was made using the model of two interpenetrating media (a gas and particles). The main assumptions are that the gas is perfect, inviscid, and does not conduct heat; the viscosity and heat transfer can be taken into account only in the interaction between the gas and the particles; and the particles do not interact with one another. (11 refs.)

71623 Calculation of gas flow in a Laval nozzle in the presence of nonequilibrium physiocochemical processes. M.Ya.Ivanov, V.A.Sal'nikov.
Fluid Dyn. (USA), vol.17, no.4, p.637-40 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.173-7 (July-Aug. 1982). [received: April 1983]
An explicit divergence difference scheme of third order of approximation with respect to the spatial variables is used to calculate two-dimensional steady flows of an inviscid gas that does not conduct heat in contracting-expanding nozzles in the presence of nonequilibrium physicochemical processes. The flow structure is demonstrated for a three-component vibrationally nonequilibrium gas mixture in planar Laval nozzles with different radii of curvature of the nozzle profile in the neighborhood of the critical section. (15 refs.)

71624 Experimental investigation of flow rate and thrust characteristics of a four-nozzle ejector with swirling flow. Yu.A.Lashkov, E.A.Shumilkina.
Fluid Dyn. (USA), vol.17, no.4, p.649-53 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.185-9 (July-Aug. 1982). [received: April 1983]
The authors have made an experimental investigation of the thrust and the flow rate characteristics of a low-pressure ejector with swirling flow in a wider range of variation of the relative pressure difference at the active nozzles ($\sigma_{max} \approx 7$). They investigated an axisymmetric ejector with four active nozzles distributed uniformly around a circle. (4 refs.)

71625 A finite element approach for predicting nozzle admittances. R.K.Sigman, B.T.Zinn (School of Aerospace Engng., Georgia Inst. of Technol., Atlanta, GA, USA).
J. Sound & Vib. (GB), vol.88, no.1, p.117-31 (8 May 1983).
A finite element method is used to predict the admittances of axisymmetric nozzles. It is assumed that the flow in the nozzle is isentropic and irrotational, and the disturbances are small so that linear analyses apply. An approximate, two dimensional compressible model is used to describe the steady flow in the nozzle. The propagation of acoustic disturbances is governed by the complete linear wave equation. The differential form of the acoustic equation is transformed to an integral equation by using Galerkin's method and Green's theorem is applied so that the acoustic boundary conditions can be introduced through the boundary residuals. The boundary conditions are described for both straight and curved sonic lines. A two dimensional FEM with linear elements is used to solve the acoustic equation. A one dimensional FEM is also used to solve the reduced equation of Crocco (1967), and the solution verifies the sufficiency of the boundary residual formulation. Comparison between computed admittances and experimental data is shown to be quite good. (23 refs.)

47.55H Stratified flows

71626 Nonlinear stage of the shearing instability in a stratified liquid of finite depth. L.A.Ostrovskii, Yu.A.Stepanyants.
Fluid Dyn. (USA), vol.17, no.4, p.540-6 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.63-70 (July-Aug. 1982). [received: April 1983]
Considers the nonlinear problem of the generation of internal waves in a two-layer incompressible liquid of finite depth with a tangential discontinuity of the velocity. It is well known that in such a flow model (without allowance for the surface tension between the layers) the Kelvin-Helmholtz instability occurs in the region of sufficiently large wave numbers, and this usually leads to rapid development of turbulence at the interface. At smaller wave numbers there is no instability because of the stabilizing effect of the stratification. In this region there are waves with negative energy, which are unstable if allowance is made for the factors that can take energy from them. Despite their relatively small (compared with the Kelvin-Helmholtz case) growth rate, such waves are of interest for describing real oceanic processes, since they are associated with a long-wavelength instability of flows that is not restricted by the finite thickness of the transition region between the layers. (15 refs.)

71627 The kinematics of stratified mixing through internal wavebreaking. A.D.McEwan (CSIRO Div. of Atmospheric Phys., Mordialloc, Victoria, Australia).
J. Fluid Mech. (GB), vol.128, p.47-57 (March 1983).
The evolution of an internal wavebreaking event in a continuous stable stratification is examined using schlieren colour imagery combined with streak photography. For standing but strongly interacting wavemodes forced to breaking, the Richardson number defined by local gradients of density and velocity is critically low only in the immediate vicinity of the breaking region where convective overturning also occurs. Breaking and vertical mixing results from the rapid development of three-dimensional interleaving density microstructure within a confined volume which persists and gravitates to modify weakly the surrounding density distribution. Continual mixing through internal motion is seen as a widespread repetition of such events. A general description of the process is proposed and applied in two types of simple kinematical model to provide an estimate of 'mixing efficiency', the ratio of potential energy gained through stratification weakening to kinetic energy expended in motions on the scales of the mixing event. These models do not rely on an assumed similarity between momentum and buoyancy transfer. (10 refs.)

71628 Internal mixing in stratified fluids. A.D.McEwan (CSIRO Div. of Atmospheric Phys., Aspendale, Victoria, Australia).
J. Fluid Mech. (GB), vol.128, p.59-80 (March 1983).
Using experimental measurements, estimates are made of the efficiency of conversion of kinetic energy into potential energy through vertical mixing in a continuously stratified fluid. In the experiments kinetic energy was supplied continuously at a rate of ϵ to a fundamental internal wave mode in a rectangularly bounded and initially linear stable stratification. Mixing resulted from the instability of this wave and its consequent 'breaking'. Potential energy was gained by the system at rate p through the gradual weakening of the stratification. The instability is predictable using wave-interaction theory, affording a means of estimating the amount of kinetic energy lost (at rate ϵ_V) to laminar viscosity without first cascading to the fine scales characteristic of turbulent mixing. (17 refs.)

71629 Statistical study of the grid zone behavior in a shallow gas-solid fluidized bed using a mini-capacitance probe. N.Yutani, T.C.Ho, L.T.Fan, W.P.Walawender, J.C.Song (Dept. of Chem. Engng., Kansas State Univ., Manhattan, KS, USA).
Chem. Eng. Sci. (GB), vol.38, no.4, p.575-82 (1983).
The behavior of the grid zone in a shallow-air-sand fluidized bed was studied by means of a mini-capacitance probe coupled with the on-line correlation technique. Experiments were carried out in a bed with a diameter of 203 mm. The bed had a height of 50 mm and was operated at different air flow rates. A perforated 'plexiglas' plate with a hole diameter of 1.59 mm and a thickness of 9.53 mm was used as the distributor. The technique has been found to be effective in determining locally or microscopically the jet penetration depth and the dead zone height. The phenomenon of jetting in a shallow gas-solid fluidized bed is described semi-quantitatively. (19 refs.)

71630 Nonstationary movement of solids in a compressible viscous liquid. O.S.Basmat.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.4, p.36-40 (1983). In Ukrainian.
The problem of nonstationary movement is stated on the basis of general solutions of the Navier-Stokes linearized equations. The movement of a cylinder at initial time moments is studied. (8 refs.)

71631 Flow of electrically charged aerosols past bodies. A.B.Vatazhin, V.A.Likhter, V.I.Shul'gin.
Fluid Dyn. (USA), vol.17, no.4, p.547-54 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.71-9 (July-Aug. 1982). [received: April 1983]
An experimental investigation was made of the flow of electrically charged aerosols with solid or liquid disperse phase past bodies. Air flows with solid particles (sand, iron) and water drops were produced by special apparatus. The regimes in which the disperse particles and the bodies were charged or neutral were studied. A system of dimensionless numbers and their values are indicated for the different gas-dynamic and electric flow regimes. The main features of the flows are explained and the integrated electric characteristics of the bodies determined. The possibility of controlling the flow of a dispersion medium by means of electric fields is demonstrated. It is shown that the inductive charging of liquid films near sharp edges of a body has a strong influence on the electric characteristics of the body (when air with water drops flows past it). (15 refs.)

71632 Study of the drag of a throttle in the film boiling of a cryogenic liquid flowing in a horizontal pipe. S.K.Dymenko, A.A.Kurilenko, S.S.Kolesnikov.
J. Eng. Phys. (USA), vol.43, no.2, p.833-6 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.186-90 (Aug. 1982). [received: April 1983]
A one-dimensional model is used to calculate the parameters of a two-phase flow and generalize test data on discharge coefficients. (4 refs.)

71633 Ambiguity of the hydrodynamic characteristics (HDC) of boiling channels in cryogenic units. A.I.Ageev, V.F.Burinov, S.I.Zinchenko, Yu.P.Filippov (Joint Inst. of Nuclear Res., Dubna, USSR).
J. Eng. Phys. (USA), vol.43, no.2, p.837-40 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.190-5 (Aug. 1982). [received: April 1983]
Criteria are obtained for the ambiguity of HDC of boiling channels which allow for local inlet and outlet drag. Results of calculations presented for the most commonly used cryogens indicate the possible ambiguity of the HDC. (6 refs.)

71634 Experimental study of the drag of a two-phase helium flow in channels. I.P.Vishnev, L.N.Migalinskaya, I.B.Lebedeva (All-Union Sci.-Res. Inst. of Helium Engng., Moscow).
J. Eng. Phys. (USA), vol.43, no.2, p.841-6 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.195-201 (Aug. 1982). [received: April 1983]
Results are presented from an experimental study of the drag of a turbulent two-phase helium flow in a horizontal channel under adiabatic conditions. (9 refs.)

71635 Modeling of mass-exchange processes taking into account fluctuations of the physicochemical parameters. F.G.Akhmadiev, A.A.Aleksandrovskii, I.N.Dorokhov (S.M. Kirov Kazansk Inst. of Chem. Technol., D.I. Mendeleev Inst., Moscow, USSR).
J. Eng. Phys. (USA), vol.43, no.2, p.908-13 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.274-80 (Aug. 1982). [received: April 1983]
The Kolomogorov-Fokker-Planck equation is used to describe the kinetics of mass exchange, taking into account fluctuations of the main physical and the chemical parameters. The solution of the problem by classical methods, using averaging of the turbulent motion and averaging in the mechanics of dis-

persed media, is difficult. The authors present a simplified method which uses the theory of Markov diffusion processes. (11 refs.)

71636 Slow motion of a micropolar fluid through a porous sphere bounded by a solid sphere. B.S.Bhatt (Dept. of Maths., Univ. of the West Indies, St. Augustine, Trinidad).
Proc. Indian Acad. Sci. Math. Sci., vol.91, no.3, p.211-16 (Nov. 1982). [received: May 1983]
Examines the slow motion of a micropolar fluid produced by the relative motion of a solid sphere to an inside porous sphere. The result extends the Cunningham's problem to micropolar fluid when the inner sphere is porous with prescribed radial suction/injection velocity at the surface of the sphere. The result can also be taken as an extension of the work of Ramkissoon and Majumdar (1975) when the fluid is bounded at a radius $r=b$ $(b>a)$ but the solid sphere is replaced by a porous sphere. The force experienced by the inner sphere has been calculated and particular cases of interest have been deduced. (9 refs.)

47.55M Flow through porous media

71637 Theory and experiment on the three-dimensional motion of a freely suspended spherical particle at the entrance to a pore at low Reynolds number. Z.Dagan, S.Weinbaum, R.Pfeffer (City Coll., City Univ. of New York, New York, NY, USA).
Chem. Eng. Sci. (GB), vol.38, no.4, p.583-96 (1983).
Examines the three dimensional approach of a neutrally buoyant sphere of any size to a circular hole in a plane wall at very low Reynolds number. The analysis differs from previous studies, largely applied to the multipore filter, in that the authors investigate the three dimensional hydrodynamic interaction of the sphere with the entrance geometry of the pore in the limit of zero inertia. The problem is first exactly formulated as the linear superposition of fundamental Stokes flows for rotation and translation of the sphere and flow past a stationary sphere. Approximate solutions are then obtained for the deviation of sphere trajectories from fluid stream lines and the results compared with laboratory model experiments in a low Reynolds number settling tank. The theory and experiment show that because of the hydrodynamic interaction sphere trajectories and fluid streamlines deviate significantly as the opening is approached, that all spheres eventually enter the pore regardless of their initial position, but that a non-uniform concentration profile develops with large increases in concentration near the walls of the orifice in the vicinity of the opening. The results provide a basic mechanism to explain the onset of Fahraeus phenomenon for red cells entering small blood vessels and glass tubes. (22 refs.)

71638 Convective instability of a homogeneous fluidized bed. Yu.P.Gupalo, Yu.S.Ryazantsev, Yu.A.Sergeev.
Fluid Dyn. (USA), vol.17, no.4, p.519-25 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.39-46 (July-Aug. 1982). [received: April 1983]
Convective motions of the phases in a homogeneous fluidized bed are considered. The motions of the phases are described by a simple model of two ideal interpenetrating interacting fluids. The model admits an increasing concentration of the solid particles with the height, which leads to circulatory flows. Approximate equations of motion of the liquid and the solid particles are obtained, and these are analogous to the Boussinesq approximation in the case of natural convection in a pure liquid. The equations contain a parameter which is analogous to the Rayleigh number and characterizes the stability of the layer. An approximate analytic solution to the corresponding eigenvalue problem is found. The spectrum of Rayleigh numbers and the sizes of the convective cells are determined. (16 refs.)

71639 Fluidization of an inhomogeneous granular layer in a field of centrifugal forces. N.N.Bobkov.
Fluid Dyn. (USA), vol.17, no.4, p.534-9 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.56-62 (July-Aug. 1982). [received: April 1983]
Considers a general theory of fluidization based on a continuum model of a rigid-plastic body and the condition of limiting equilibrium can be used to solve the problem of the transition to a suspended state of an inhomogeneous granular layer through which a liquid or gas flows in a field of centrifugal forces. The author shows that depending on the nature of the inhomogeneities and their position, there can either be uniform fluidization or else the formation of a discontinuity in the bed. The centrifugal acceleration is created by the rotation about its symmetry axis of a hollow circular cylinder on whose inner surface there is an annular layer of a free-flowing medium. The fluidizing agent is supplied uniformly through the porous cylindrical surface, which is impermeable for particles of the solid phase. The fluid moves radially in the direction of the cylinder axis. (5 refs.)

71640 Vorticity of the velocity field for flow in a porous medium with random inhomogeneities. M.I.Shvidler.
Fluid Dyn. (USA), vol.17, no.4, p.619-21 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.157-60 (July-Aug. 1982). [received: April 1983]
The vorticity field of the flow velocity in a porous medium with random inhomogeneities is considered in the correlation approximation of perturbation theory. The correlation tensor of the vorticity, the correlation between the vorticity and the permeability field, and the circulation of the velocity are calculated for three-and two-dimensional flows. (1 ref.)

71641 Self-similar solution to a problem of axisymmetric motion of gas through a porous medium in the case of a quadratic law of resistance. N.A.Kudryashov, V.V.Murzenko.
Fluid Dyn. (USA), vol.17, no.4, p.631-4 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.168-71 (July-Aug. 1982). [received: April 1983]
The results of solution of the self-similar problem of planar flow of gas through a porous medium in the case of a quadratic law of resistance are generalized to the case of axisymmetric motion. The equation in similarity variables for the velocity of isothermal gas flow is reduced to an equation having cylindrical functions as solution. Analytic dependences of the pressure and the gas velocity on the coordinate and time are obtained for a given flow rate of the gas at the coordinate origin and for zero initial gas pressure in the porous medium. (9 refs.)

71642 The boundary correction for the Rayleigh-Darcy problem: limitations of the Brinkman equation. D.A.Nield (Dept. of Math., Univ. of Auckland, Auckland, New Zealand).
J. Fluid Mech. (GB), vol.128, p.37-46 (March 1983).
The no-slip condition on rigid boundaries necessitates a correction to the critical value of the Rayleigh-Darcy number for the onset of convection in a horizontal layer of a saturated porous medium uniformly heated from below. It is shown that the use of the Brinkman equation to obtain this correction is not justified, because of the limitations of the equation. These limitations are discussed in detail. An alternative procedure, based on a model in which the porous medium is sandwiched between two fluid layers, and the Beavers-Joseph boundary condition is applied at the interfaces, is described, and an expression for the correction is obtained. It is found that the correction can be of either sign, depending on the relative magnitudes of the parameters involved. (23 refs.)

71643 The use of the variational principle in the solution of Stokes flow problems in fibrous filters. R.C.Brown (Health & Safety Executive, Sheffield, England).
J. Phys. D (GB), vol.16, no.5, p.743-54 (14 May 1983).
The variational principle is applied to trial functions containing infinite series or orthogonal functions, in order to describe Stokes flow through systems with a symmetry too low to permit an exact analytical solution of the flow equation. The problem of Poiseuille flow between two laminae is solved exactly by this method, to illustrate its power. The method is then applied to the problem of flow through a two-dimensional symmetrical fibrous filter, where it results in a many-fibre model of a filter with a continuous stream function, and can be used to calculate the pressure drop across the filter. The model is limited to fibres that are flattened in the flow direction. Finally, the principle is applied to a description of the macroscopic flow pattern through a filter pleat. Reasonable agreement with simple analogue methods is found both for the pressure drop and the flow pattern. (8 refs.)

71644 Kinetics of isothermal evaporation of a porous or dispersed body. B.V.Deryagin, V.M.Starov, D.V.Fedoseev (Inst. of Phys. Chem., Acad. of Sci., USSR).
J. Eng. Phys. (USA), vol.43, no.2, p.900-7 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.265-73 (Aug. 1982). [received: April 1983]
Considers the evaporation of a porous body which consists initially of spheres of identical radii. The authors find the dependence of the velocity of motion of the boundary of the body on the external parameters. (3 refs.)

71645 On the Riemann-Hilbert's boundary value problem, for flow through porous inhomogeneous media. M.T.Orasanu (Vocational School No.3, Bucharest, Rumania).
Mech. Res. Commun. (GB), vol.10, no.1, p.27-36 (Jan.-Feb. 1983).
Previous results concerning Emile Picard's Great Theorem, used for the study of plane, stationary flow with free and seepage surfaces in porous inhomogeneous media of the second type are extended. (6 refs.)

47.60 FLOWS IN DUCTS, CHANNELS, AND CONDUITS

(for biological fluid dynamics, see 87.45)

71646 Regulating valves: the noise problem. I. K.Gruner, R.W.Dam.
Automatie (Netherlands), vol.26, no.12, p.448-58 (Dec. 1982). In Dutch. [received: April 1983]
The mathematical formulae used in calculating the flow of gases, steam, and iquids through pipe restrictions are reviewed. The possible sources of noise from regulating valves are mentioned. Curves are given which show the variation in noise with the pressure drop. In liquids cavitation produces noise while turbulence produces noise in gases. Noise can be reduced by multistage restrictions in valves. (no refs.) *T.S.E.T.*

71647 On the theory of dispersion of a solute during laminar flow in tubes. V.Lisy, L'.Turna (Faculty of Natural Sci., Univ. of P.J. Safarik, Kosice, Czechoslovakia).
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.5, p.480-4 (1983).
The problem of the diffusion of a solute during laminar flow through a circular tube is solved. A new method of the approximate solution of the corresponding diffusion equation is used. The analytical solution found is compared to previous ones. It is shown that this solution involves the well-known solutions of Taylor-Aris and Maron (1975). The dispersion of a radioactive solute was found which differs from that known in Maron's model. The solution of the problem is also given for the case of the flow between plane parallel walls. (8 refs.)

71648 The dependence of coefficients in the relation of velocity ratio on parameters of a capsule. J.Myska, P.Vlasak (Inst. of Hydrodynamics, Czechoslovak Acad. of Sci., Praha, Czechoslovakia).
Chem. Eng. Sci. (GB), vol.38, no.4, p.547-55 (1983).
The velocity of a capsule in a pipeline is usually plotted in most papers in graphs as a dependence of velocity ratio U_k/U on the mean liquid velocity U. In order to compare various velocity measurements there had been derived the equation $U_k/U\text{-}f(U)$ which in general case is hyperbolic containing three parameters. However for evaluation of most published results a simplified linear form of the equation with only two coefficients is good enough. Both empirical coefficients are influenced by parameters of the system like capsule-pipe diameter ratio, capsule-length diameter ratio or apparent density. (9 refs.)

71649 Flow past a thin profile in a channel with permeable working part. N.A.Marevtseva.
Fluid Dyn. (USA), vol.17, no.4, p.644-9 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.180-5 (July-Aug. 1982). [received: April 1983]
An exact solution is obtained to the problem of flow of an ideal incompressible fluid past a thin profile in a straight channel. The channel walls are continuous except for the working part, where they are permeable. (3 refs.)

71650 Density distribution of a molecular stream over surfaces of a vacuum channel. N.K.Nikulin, Yu.A.Nikitchenko.
Izv. VUZ Mashinostr. (USSR), no.3, p.67-71 (1983). In Russian.
Results are presented of investigating the influence of geometric and sorption characteristics of a vacuum channel on density distribution of a molecular stream, admitted in different cross-sections of this channel. The analyses were performed for channels, represented by coaxial cylindrical surfaces, by a method of angular coefficients. Recommendations are made for ensuring a uniform density distribution of the molecular stream in a vacuum channel, evacuated from one end. (5 refs.) *Z.F.V.*

71651 Peristaltic flow of viscoelastic liquids. G.Bohme, R.Friedrich (Inst. fur Stromungslehre und Stromungsmaschinen, Hochschule der Bundeswehr Hamburg, Hamburg, Germany).
J. Fluid Mech. (GB), vol.128, p.109-22 (March 1983).
The mechanism of peristaltic transport of an incompressible viscoelastic fluid by means of an infinite train of sinusoidal waves travelling along the wall of the duct is studied in the case of a plane flow. The main assumptions are that the relevant Reynolds number is small enough to neglect inertia forces, and that the ratio of the wavelength and the channel height is large, which implies that the pressure is constant over the cross-section. For sufficiently small values of the ratio of the wave amplitude and the mean height of the channel, details of the fluid motion are studied analytically within a second-order approximation with respect to the amplitude ratio. Under these conditions the integral constitutive equation of finite linear viscoelasticity is relevant. Particular attention is given to the pressure-discharge characteristics of the peristaltic pump and to the pumping efficiency. The results are influenced by specific values of the complex viscosity of the fluid, which can be determined using standard rheometers. (10 refs.)

71652 Secondary instability of wall-bounded shear flows. S.A.Orszag, A.T.Patera (MIT, Cambridge, MA, USA).
J. Fluid Mech. (GB), vol.128, p.347-85 (March 1983).
An analysis is given of a secondary instability that obtains in a wide class of wall-bounded parallel shear flows, including plane Poiseuille flow, plane Couette flow, flat-plane boundary layers and pipe Poiseuille flow. In these flows it is shown that two-dimensional finite-amplitude waves are (exponentially) unstable to infinitesimal three-dimensional disturbances. This secondary instability seems to be the prototype of transitional instability in these flows in that it has the characteristic (convective) timescales observed in the typical transitions. In the case of plane Poiseuille flow, two-dimensional nonlinear equilibria and quasi-equilibria exist, and the stability of the secondary flow is determined by a three-dimensional linear eigenvalue calculation. In flows without equilibria (e.g. pipe flow), a time-dependent stability analysis is performed by direct spectral numerical calculation of the incompressible three-dimensional Navier-Stokes equations. The energetics and vorticity dynamics of the instability are discussed. (45 refs.)

71653 Simple mathematical model of flow in cylindrical tube system. F.Jirous (CVUT, Praha, Czechoslovakia).
Jad. Energ. (Czechoslovakia), vol.29, no.4, p.121-5 (April 1983). In Czech.
A nonlinear differential equation is derived and numerically solved. It concerns the calculations of flow in the system which is composed of a cylindrical header with a radial or axial inlet, a cylindrical core and a cylindrical header with a radial outlet. In case of symmetrical flow the irregularity flow distribution is determined. (7 refs.)

71654 Inertia effect on deposition of charged particles in a parallel-plate channel. R.Y.Chen, H.E.Pawel, W.C.Chen (N.J. Inst. of Technol., Newark, NJ, USA).
Powder Technol. (Switzerland), vol.34, no.2, p.249-53 (March-April 1983).
The effect of inertia forces on the deposition of highly charged fine particles of sizes less than 20 μm in a parallel-plate channel has been analyzed numerically for uniform and fully-developed flows. The deposition is primarily due to space charge alone and the image and gravity forces are not included in the analysis. A charge-inertia parameter n (ranging from 0 to 1) was defined to characterize the flow deposition phenomena. It was found that for n less than 0.1 the effect of inertia forces may be neglected and that the fraction of deposition near the entrance of the channel deviates substantially from the result neglecting the inertia effect. (5 refs.)

71655 Complementary variational principles for Poiseuille flow of an Oldroyd fluid. M.A.Gopalan (Dept. of Maths., Nat. Coll., Trichy, India).
Proc. Indian Acad. Sci. Math. Sci., vol.91, no.3, p.195-9 (Nov. 1982). [received: May 1983]
The complementary variational principles are given for the Poiseuille flow of an Oldroyd fluid by taking the pressure gradient to be exponentially increasing with time and the bounds on the flux are obtained. (6 refs.)

71656 The hydraulic resistance of a horizontal rectangular channel with stratified two-phase flow. P.V.Besfamil'nyi, A.I.Leont'ev, G.V.Tsiklauri.
Therm. Eng. (GB), vol.29, no.8, p.448-51 (Aug. 1982). Translation of: *Teploenergetika (USSR)*, vol.29, no.8, p.65-7 (Aug. 1982). [received: April 1983]
In designing the flow sections of heat engines and mass transfer apparatus in which there is a wavy liquid film in a carrier flow of gas, calculation of the hydraulic resistance is of great importance. The waves at the surface of the moving film lead to a considerable increase in pressure losses in the channels and, consequently, to an increase in power costs for transporting the medium. Despite the many investigations no reliable universal method of calculation has yet been put forward, due to the strong dependence of the parameters of the wave structure on flow conditions. The authors present the results of investigating hydraulic resistance with cocurrent turbulent air flow and a wavy film in a horizontal duct 2.3 m long, 19 mm high and 165 mm wide. (12 refs.)

71657 Evaluation and calculation of gas flow through axially symmetric tubes. L.Fustoss (Phys. Inst., Tech. Univ. of Budapest, Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.13-16 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
For vacuum techniques, the rate of gas flow is the most important quantity. In the free molecular flow region there are known correct results and approximate formulae for the transmission probabilities. In the near-free molecular flow region Monte-Carlo results and extrapolation terms are available. The precision required or the achievable accuracy determines the complexity of the calculations. For free molecular flow transmission probabilities of axially symmetric tubes a procedure to increase the accuracy is described. In the near-free molecular flow region Monte-Carlo results are presented with an indication of extrapolation possibilities. In the transmission probability calculations allowance is made for the roughness of the tube wall. (9 refs.)

47.65 MAGNETOHYDRODYNAMICS AND ELECTROHYDRODYNAMICS

(for MHD in plasma, see 52.30)

71658 Instability of horizontal fluid interface in a perpendicular electric field: observational study. H.Terasawa, Y.H.Mori, K.Komotori (Dept. of Mech. Engng., Keio Univ., Yokohama, Japan).
Chem. Eng. Sci. (GB), vol.38, no.4, p.567-73 (1983).
In order to obtain some insight into the potential applicability of electrohydrodynamic augmentation to the direct-contact heat or mass exchange between stratified fluids, observations were made of the phenomena related to the field-induced instabilities at stationary interfaces between air and slightly-conducting oil, slightly-conducting oil and conducting aqueous solution, and two slightly-conducting oils. Established theories assuming the interface conducting or charge-free failed to predict the onset of instability under DC or AC fields in the last fluid system of the three. The geometries and fluid motions at disturbed interfaces are described laying stress on those, found in the last fluid system, which are very peculiar and have not been reported so far. (11 refs.)

71659 Stabilization of bubble-liquid processes by an electric field. V.A.Naletova.
Fluid Dyn. (USA), vol.17, no.4, p.491-7 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.5-12 (July-Aug. 1982). [received: April 1983]
The stability of bubble-liquid and sedimentation processes in the presence of an electric field is investigated. To describe such processes in the case of polarizable particles or bubbles in a dielectric liquid in the presence of an electric field, the 'multivelocity' model of a multiphase mixture interacting with an electric field has been used. Gogosov, Naletova, and Shaposhnikova (1980) have shown that a transition can take place to a regime of uniform ascent or sinking of the particles in the field of a planar capacitor. A criterion of stability of such a regime in an electric field is derived. It is shown that if the electric field is sufficiently strong (stronger than a certain critical E_{cr}) the regime is stable. The stability arises because in a mixture of polarizable phases in the presence of an electric field the difference between the permittivities results in a force F which acts on the disperse phase. (5 refs.)

71660 Flow of a stream containing charged inertial particles past a conducting sphere. O.K.Varentsov.
Fluid Dyn. (USA), vol.17, no.4, p.504-9 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.21-6 (July-Aug. 1982). [received: April 1983]
The problem of the flow of a hydrodynamic stream containing electrically charged particles past a conducting sphere is solved. The influence of the volume density of the electric charge and the potential of the sphere on the capture coefficient η is determined for different values of the inertia parameter of the particles and different drag laws for them. It is shown that for an earthed sphere η can appreciably exceed unity. In the formulation of the problem, it is assumed that the region of electrogasdynamic flow is bounded by two elecrode grids, which simulate the exit of the source of charged particles and the surrounding electric conditions. The velocity field near the sphere is assumed irrotational. The problem is solved numerically. (7 refs.)

71661 Hall effects on nonlinear Hartmann-Ekman layers. K.N.Venkatasiva Murthy (Sri Krishnadevaraya Univ., Anantapur, India).
Int. J. Eng. Sci. (GB), vol.21, no.7, p.841-5 (1983).
Considers the magnetohydrodynamics of a rotating, incompressible, electrically conducting fluid bounded by a single infinite insulating disk, subjected to a differential rotation. The magnetic field is sufficiently large and the motion of the charged particles across the magnetic field is hindered resulting in the existence of Hall currents in a direction perpendicular to both electric and magnetic fields. These Hall currents arise in several astrophysical situations and in MHD power generation. Taking the Hall currents into consideration, a nonlinear theory of the hydromagnetic flow problem has been developed using the method of matched asymptotic expansions. The Hall currents are shown to produce several important and interesting effects on the thickness of the boundary layers like controlling suction velocity at the outer edge of the magnetic diffusion region and eliminating the occurence of negative rotational velocity at the transitional edge of the two boundary layers. (4 refs.)

71662 Electrohydrodynamic generator, a study of short-circuit current in relation to the length between the injector and the collector and to the liquid temperature. G.Touchard, A.Il Idrissi, P.Humeau (Lab. of Phys. & Fluid Mech., Univ. of Poitiers, Poitiers, France), J.Sauniere.
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.71-9
The study concerns the dependence of the current delivered by an electrohydrodynamic generator on two parameters: the temperature of the dielectric liquid and the length of the insulating tube which separates the collector reservoir from the capillaries. Under constant liquid flow, the current increases with temperature, its value doubling when the temperature is raised from 30°C to 50°C. The influence of the length of insulating tube is such that maximum current is obtained when the length is shortest, thus confirming the theory that was proposed. (7 refs.)

71663 Flame spread in an opposed flow with a linear velocity gradient. I.S.Wichman (Dept. of Mech. & Aerospace Engng., Princeton Univ., Princeton, NJ, USA).
Combust. & Flame (USA), vol.50, no.3, p.287-304 (April 1983).
A theoretical model is developed for estimating the rate of flame spread under conditions of heat-transfer control with account taken of the fact that the gas velocity is not uniform. It is shown that the functional dependence of the spread rate on parameters such as the external gas velocity is modified from that obtained in the classical study of J.N. de Ris (1969). The modified formula is capable of lending interpretation to previously anomalous experimental observations. (12 refs.)

71664 A composite model for the conserved scalar PDF [of turbulent reacting flows]. E.Effelsberg, N.Peters (Inst. fur Allgemeine Mech., Rheinisch-Westfalische Tech. Hochschule Aachen, Aachen, Germany).
Combust. & Flame (USA), vol.50, no.3, p.351-60 (April 1983).
A parametric expression for the conserved scalar probability density function (PDF) is derived on the basis of a physical interpretation of the turbulent signal. The scalar signal is split into three parts: a fully turbulent part, a superlayer part, and a outer flow part. Each part is represented by a different form of the PDF. The composite PDF which is obtained by adding these parts together has four parameters in addition to the intermittency factor. It can be integrated so that algebraic relations between these parameters and the first four moments are obtained. Application of the formulation to J.C. LaRue's and P.A. Libby's measurements (1974) in the plane turbulent wake indicates the existence of transitions that are interpreted as internal superlayers far inside the turbulent flow. (16 refs.)

71665 Hydrodynamics of films of surface-active substances. N.G.Taktarov.
Fluid Dyn. (USA), vol.17, no.4, p.612-18 (July-Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Mekh. Zhidk. & Gaza*, vol.17, no.4, p.150-7 (July-Aug. 1982). [received: April 1983]
The author derives equations describing the motion of a film of surface-active substance at the interface of two three-dimensional phases. The film is assumed to consist of m two-dimensional phases and n components that react chemically with one another. The three-dimensional phases are assumed to be single phases and consist of n components, which can be adsorbed and desorbed at the interface. The interface exchanges matter, momentum, and energy with the three-dimensional phases and is thus an open system. Using the methods of the thermodynamics of nonequilibrium processes, the author obtains expressions for the two-dimensional stress tensors of all phases the diffusion fluxes of the surface-active substance in the two-dimensional phases, the heat fluxes within the phases and the heat transfer between the phases, the rates of the surface chemical reactions and the two-dimensional phase transitions. (18 refs.)

47.75 RELATIVISTIC FLUID DYNAMICS

71666 Some remarks on conservative symmetric-hyperbolic systems governing relativistic theories. A.Strumia (Istituto di Matematica Applicata, Univ. di Bologna, Bologna, Italy).
Ann. Inst. Henri Poincare Sect. A (France), vol.38, no.2, p.113-20 (1983).
It is shown that for the covariant quasi-linear hyperbolic systems of conservation laws, endowed with a supplementary balance equation, which exhibit a special structure, some results obtained in a previous paper can be proved in a simpler way by choosing a field dependent congruence as time direction instead of a field independent fourvector. In the case of fluid dynamics it is shown that the suitable congruence is represented by the fluid fourvelocity. (6 refs.)

47.80 INSTRUMENTATION FOR FLUID DYNAMICS

71667 Visualization of multijet impingement flow. K.R.Saripalli (McDonnell Douglas Corp., St. Louis, MO, USA).
AIAA J. (USA), vol.21, no.4, p.483-4 (April 1983).
Flow visualization experiments were conducted in water as the working medium to study multijet impingement flows with fountain formation. The visualization technique uses fluorescein-sodium, a fluorescent dye, as tracer fluid and illumination by a sheet of light obtained by spreading a laser beam. Streakline photographs were also taken using air bubbles as tracer particles. Stagnation-line patterns were recorded for the cases of two-, three-, and four-jet configurations and compared with theoretical predictions. (3 refs.)

71668 An air flow rig for use in hot element and other anemometer experiments. M.J.Turner (Dept. of Electrical Engng., Univ. of the Witwatersrand, Johannesburg, S Africa).
Int. J. Electr. Eng. Educ. (GB), vol.20, no.2, p.169-76 (April 1983).
An apparatus used in undergraduate instrumentation teaching is described. A small wind tunnel creates air speeds up to 12 m/s. A pitot tube is used as a reference against which a hot wire anemometer is compared for linearity and transient response. The experiment serves to introduce non-ideal systems. (2 refs.)

71669 Steady shallow flow over curved beds. N.S.Sivakumaran, T.Tingsanchali, R.J.Hosking (Asian Inst. of Technol., Bangkok, Thailand).
J. Fluid Mech. (GB), vol.128, p.469-87 (March 1983).
The validity of recent shallow-flow equations with bed curvature is examined. Subcritical, critical and supercritical steady-flow solutions are identified, and the point of critical flow on the bed located, in terms of a generalized Froude number. Experiments on steady flow over both a symmetric and unsymmetric bed profile show that the theory satisfactorily predicts the free-surface and bed-pressure profiles over $-2 \lesssim \kappa h \leq 0.54$ (where κ is the bed curvature and h is the flow depth normal to the bed). (11 refs.)

71670 Method of obtaining stable flow rates in test systems. V.B.Korolev, L.M.Korsunskii, A.F.Semenchenko.
Meas. Tech. (USA), vol.25, no.8, p.650-1 (Aug. 1982). Translation of: *Izmer. Tekh. (USSR)*, vol.25, no.8, p.26-7 (Aug. 1982). [received: April 1983]
In systems for checking and calibrating flowmeters and devices measuring local velocity and velocity fluctuation it is necessary to provide stable flows with reproducible hydrodynamic characteristics. A method of stabilizing the flow rate by means of an automatic-control system with feedback from the flow rate and electromagnetic flowmeters of elevated accuracy as transducers in a test system employing a free jet for examining and calibrating velocity-fluctuation meters is considered. The system provides control of the speed at the nozzle over the range 1:200. (3 refs.)

71671 Calibration of a jet flowmeter on a substitute liquid. V.M.Levin.
Meas. Tech. (USA), vol.25, no.8, p.652-3 (Aug. 1982). Translation of: *Izmer. Tekh. (USSR)*, vol.25, no.8, p.28-9 (Aug. 1982). [received: April 1983]
Specialized jet flowmeters for liquid Freon have been considered. The jet method of measurement consists in using the impact pressure arising on contact between a jet emerging from a nozzle and a baffle as the flow-rate signal. The theory of calibration on a substitute liquid is presented and practical verification of the theoretical formulas is discussed. It is concluded that the jet method of flow rate measurement is promising for liquids for which direct calibration is difficult. (2 refs.)

71672 Dispersed powder flow through vertical pipes. G.A.Irons, J.-S.Chang (McMaster Univ., Hamilton, Ontario, Canada).
Powder Technol. (Switzerland), vol.34, no.2, p.233-42 (March-April 1983).
A novel transducer, based on an electrical capacitance principle, was used to measure the instantaneous volume-averaged in situ particle fraction and thereby determine the volume-averaged particle velocities. It was clear that the 450 μm diameter sand particles were being accelerated to a terminal slip velocity with respect to the gas phase. The static pressure drop over the same length was also measured and interpreted by means of a one-dimensional, two-phase model. The contributions to the overall pressure drop of gravitational forces on the particle, acceleration of gas and particles and the coupling force between gas and particles were calculated. The gas-particle drag coefficients were within 30% of those of single particles. A predictive model was also developed which yielded good results with the experimental data. (7 refs.)

71673 Non-intrusive measurement of aerodynamic flow.
Rev. Polytech. (Switzerland), no.3, p.201, 203 (1983). In French.
Describes a laser-based flow meter devised by the Office National d'Etudes et de Recherches (ONERA) for non-intrusive measurement of rates of flow at for example transonic and supersonic velocities, in hot gases up to 2700°C, etc. Two laser beams at slightly different frequencies are arranged to cross so as to produce a space, situated in the flow, and of the order of 20 μm dia. and 800 μm length, in which there is a system of moving interference fringes. Sub-microscopic particles (typically of incense smoke, dioctylephtalate, ZrO_2, TiO_2, etc.) are injected into the flow and are detected during their passage through the fringes by two photomultipliers with suitable filters; the resulting information is processed to provide a linear indication of the velocity and to indicate turbulence of velocity, with accuracy of the order of 1%. (no refs.)

51.00 KINETIC AND TRANSPORT THEORY OF FLUIDS; PHYSICAL PROPERTIES OF GASES

51.10 KINETIC AND TRANSPORT THEORY

71674 A rough-hard-sphere theory for diffusion in supercritical carbon dioxide. S.-H.Chen (Dept. of Chem. Engng., Univ. of Rochester, Rochester, NY, USA).
Chem. Eng. Sci. (GB), vol.38, no.4, p.655-60 (1983).
A rough-hard-sphere (RHS) theory is found to successfully account for the effects of molecular rotation and dynamically correlated molecular collisions on self-diffusion in carbon dioxide at temperatures from 35 to 100°C and pressures from 70 to 246 atm. The Mathur-Thodos empirical equation finds its molecular basis within the framework of the RHS theory. The theory is also applicable to tracer diffusion of benzene in carbon dioxide at 35-55°C and 91-158 atm, where densities are greater than 0.500 g/cm^3. Its failure at lower densities suggests that the molecular dynamics computer result of self-diffusion is inadequate for describing the effect of collective molecular motion encountered in tracer diffusion across the entire density range. Further computer work is recommended which will refine the prediction of tracer diffusion in supercritical fluids using the RHS theory. (25 refs.)

71675 Development of a new correlation for binary gas phase diffusion coefficients. P.C.Singh (Dept. of Chem. Engng., Auburn Univ., AL, USA), S.Singh.
Int. Commun. Heat & Mass Transfer (GB), vol.10, no.2, p.123-40 (March-April 1983).
In the present investigation a simple and widely applicable correlation for the estimation of binary gas phase diffusion coefficient has been developed. The correlation needs only well known parameters and therefore is easier to use in comparison with other correlations available which need parameters and factors not known for many substances and therefore need experimental determination first. (22 refs.)

71676 Excess second virial coefficients for nitromethane and cyclohexane at 373.2K and nitroethane and cyclohexane at 298.25, 323.16 and 348.38K. K.N.Marsh, H.P.D.Rogers (Dept. of Chem., Univ. of New England, Armidale, NSW, Australia).
Ind. & Eng. Chem., Fundam. (USA), vol.22, no.1, p.1-4 (Feb. 1983).
The excess second virial coefficients of nitromethane and cyclohexane at 373.2K and nitroethane and cyclohexane at 298.25, 323.16 and 348.38K have been measured by use of a differential technique. The excess second virial coefficients are large and positive. The results for both pure nitromethane and the mixtures are satisfactorily predicted by the correlation proposed by J.G. Hayden and J.P. O'Connell (1975). (11 refs.)

71677 Generalized treatment of self-diffusivity for the gaseous and liquid states of fluids. H.Lee, G.Thodos (Northwestern Univ., Evanston, IL, USA).
Ind. & Eng. Chem., Fundam. (USA), vol.22, no.1, p.17-26 (Feb. 1983).
Self-diffusivity measurements reported in the literature for 27 fluids have been critically reviewed and used to develop a method for predicting this transport property for all fluid conditions including the liquid state. In this treatment, a dimensional analysis produced the self-diffusivity parameter, $\delta = M^{1/2}/P_c{}^{1/2}v_c{}^{5/6}$, which, with the exception of helium-3, permitted the development of a unique relationship between $\mathcal{D}\delta/T_R$ vs. ρ_R for reduced densities, $\rho_R<1.0$. For $\rho_R>1.0$, the dimensionless ratio $G=(X^*-X)/(X^*-1)$ has been adopted for a generalized treatment with $\mathcal{D}\delta/T_R$ where $X=\rho_R/T_R{}^{0.1}$, and which becomes constant along the solid melting curve to define X2u at the triple-point temperature. (94 refs.)

71678 Statistical mechanics of one-dimensional systems. III. Multicomponent gas with Kac's potential. T.Takano, K.Ikeda (Dept. of Appl. Phys., Osaka Univ., Suita, Japan).
Prog. Theor. Phys. (Japan), vol.69, no.2, p.415-30 (Feb. 1983).
For pt.II see ibid., vol.67, no.6, p.1678-86 (1982). The model of one-dimensional multicomponent gas is considered in which the particles have hard cores and the (attractive) interparticle potentials are given by $-a_{ij}\gamma e^{-\gamma R}$ with $\gamma \rightarrow +0$ (a_{ij} being a positive constant characteristic of the pair i, j of species). By the method of external potential, an equation for the grand partition function for this model is obtained. By finding the largest eigenvalue of this equation, the pressure and all the other thermodynamic functions for the infinite system are exactly calculated. It is shown that this model exactly obeys the same equation of state as the one obtained in the preceding paper of this series, i.e. the natural extension of van der Waals' equation of state to the multicomponent system. (10 refs.)

71679 Analytical solutions for infrared-laser driven diffusion in polyatomic gas mixtures. N.M.Lawandy, E.W.Cumming (Div. of Engng., Brown Univ., Providence, RI, USA).
Phys. Rev. A (USA), vol.27, no.5, p.2548-54 (May 1983).
The authors use an effective bimodal velocity distribution in a five-level model to analytically examine the problem of laser-driven gas transport in mixtures of an absorbing gas and a buffer gas. Analytic expressions are given for the steady-state active-gas density distribution in a closed tube for a uniform excitation profile. The model also predicts that laser induced transport may occur without a buffer gas if collision favoring simultaneous vibrational deactivation and velocity change occur. Profiles are given for CH_3F:He mixtures when a CO_2 laser is used to excite the $Q_{12,2}$, ν_3 band absorption. (17 refs.)

51.30 THERMAL PROPERTIES OF GASES

71681 Prediction of transport properties. II. Thermal conductivity of pure fluids and mixtures. J.F.Ely, H.J.M.Hanley (Nat. Engng. Lab., NBS, Boulder, CO, USA).
Ind. & Eng. Chem., Fundam. (USA), vol.22, no.1, p.90-7 (Feb. 1983).
For pt.I see ibid., vol.20, p.323 (1981). A technique for the prediction of the thermal conductivity of nonpolar pure fluids and mixtures over the entire range of *PVT* states is presented. Calculations for the thermal conductivity require only critical constants, molecular weight, Pitzer's acentric factor, and the ideal gas heat capacity as a function of temperature for each mixture component as input. Extensive comparisons with experimental data for pure fluids and nonpolar binary fluid mixtures including paraffins, alkenes, aromatics and naphthenes with molecular weights to that of C_{24} are presented. The average absolute deviation between experiment and prediction is less than 7% for both pure species and mixtures. (84 refs.)

71682 Theoretical studies of H_2-H_2 collisions. IV. Ab initio calculations of anisotropic transport phenomena in parahydrogen gas. W.E.Kohler (Inst. fur Theoretische Phys., Univ. Erlangen-Nurnberg, Erlangen, Germany), J.Schaefer.
J. Chem. Phys. (USA), vol.78, no.8, p.4862-74 (15 April 1983).
The temperature dependence of the effective Waldmann-Snider cross sections determining the Senftleben-Beenakker effects of viscosity and heat conductivity has been studied for pH_2 gas between 10 and 200K. From ab initio nonspherical potentials of H_2-H_2, scattering matrices have been determined in close-coupling calculations. From these, the elements of the scattering amplitude matrix have been obtained and used as input quantities for the evaluation of the various Waldmann-Snider collision integrals. The results of these first ab initio numerical calculations of anisotropic transport coefficients show excellent agreement of calculated and measured effective cross sections, especially for the most recent improved version of the interaction potential. In addition, it has been shown that the polarization production cross sections are quite sensitive to the potential anisotropy. (36 refs.)

71683 Two-dimensional Gaussian core model at high temperature. F.H.Stillinger, T.A.Weber (Bell Labs., Murray Hill, NJ, USA).
Phys. Rev. A (USA), vol.27, no.5, p.2642-8 (May 1983).
The two-dimensional Gaussian core model in the high-temperature regime has been examined by two means: (1) exact high-temperature series, and (2) molecular-dynamics simulation. The former diverge but can be summed by Borel transforms. Evidence is offered that in the case of the mean potential energy per particle and the excess pressure that the Borel transforms are analytic throughout the complex plane. Furthermore, these transforms grow exponentially along the positive real axis at a rate which determines the fluid's freezing-point temperature. Approximate Borel transforms have been constructed which fit the simulation data adequately. (10 refs.)

51.50 ELECTRICAL PHENOMENA IN GASES

(see also 52. Plasma and electric discharges)

71684 A study on the measurement of electron drift velocity in metal vapour. Yontack Chung, Sung-Chul Ha.
Trans. Korean Inst. Electr. Eng., vol.31, no.12, p.206-16 (1982). In Korean.
Results are presented from an experimental study of the electron drift velocity in the K vapor on the open end heat pipe system by the inducing current method and spectroscopic measuring system. The test conditions were pressure of 3.6 to 20.1 Torr., temperature of 667 to 775K, and E/N of 10^{-16} to 10^{-15} V cm^2. The results of this study are obtained essentially the same as the extrapolated prediction curve for electron drift Velocity in the K vapor of Nakamura et al with range of E/N 10^{-17} to 10^{-16} V cm^2 and the electron drift velocity is decreased about 30% over all range which is less than that of the Na vapor. (12 refs.)

71685 Dependence of electrical conductivity of SF_6 on temperature and pressure in a strong electric field. P.Krenek (Ustav pro Elektrotech. CSAV, Prague, Czechoslovakia).
Elektrotech. Obz. (Czechoslovakia), vol.72, no.3, p.139-43 (March 1983). In Czech.
An algorithm for the calculation of electrical conductivity of a mixture of partially ionised gases is proposed based on considerations about the dependence of the electron mobility and temperature on the intensity of electric field which respects the dependence of the mixture composition on the electron temperature. The calculations were applied to the mixture of products of the decomposition of SF_6 in order to determine the dependence of the electron conductivity on pressure in a strong electric field. (9 refs.)

71686 A modified constriction model for the resistivity of a bubble curtain on a gas evolving electrode. O.Lanzi, R.F.Savinell (Dept. of Chem. Engng., Univ. of Akron, Akron, OH, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.799-802 (April 1983).
At gas evolving electrodes, the bubble curtain at the electrode surface contributes to the voltaic inefficiencies of the electrolyzer. Consequently, the structure of the bubble curtain and its effect on electrolyte resistivity is of practical importance. In order to predict the resistance of the bubble curtain several models have been suggested in the literature. Three-dimensional models pro-

vide an adequate prediction of the resistance of dilute bubble curtains with monolayer gas voidages less than 0.55. The authors propose a two-dimensional constriction model of a dense bubble curtain which is modified to account for a three-dimensional dispersed phase within the monolayer. The resulting mathematical expression behaves properly in the limits of voidage and its prediction agrees well with the limited available data. (14 refs.)

71688 Shifts of ionized-helium lines from electron collisions in dense plasmas. H.R.Griem (Lab. for Plasma, Univ. of Maryland, College Park, MD, USA).
Phys. Rev. A (USA), vol.27, no.5, p.2566-76 (May 1983).
The semiclassical impact-parameter method is used to calculate shifts of ionized helium lines in the first three spectral series caused by electrons in a plasma. These shift together with opposite and smaller shifts due to ion quadrupole interactions are in agreement with observed shifts of lines corresponding to the Paschen series of hydrogen. Adding plasma polarization shifts according to the linearized Debye model to the shifts calculated here results in overestimates by a factor of 2 for the shifts of these lines. For lines corresponding to the Balmer series such addition may be consistent with measurements, while for the Lyman series all present theoretical models are found inadequate. (23 refs.)

71689 Numerical study of overpopulation density for laser oscillation in recombining hydrogen plasmas. T.Oda (Faculty of Sci., Hiroshima Univ., Hiroshima, Japan), U.Furukane.
J. Quant. Spectrosc. & Radiat. Transfer (GB), vol.29, no.6, p.553-9 (June 1983).
Overpopulation densities Δn_{ij}, which are defined as the differences between the population densities per unit statistical weight of the upper and lower excited levels i and j, are calculated as a function of the electron density n_e for various electron temperatures T_e in recombining hydrogen plasmas. Calculations have been made for line pairs with principal quantum numbers (2,3), (3,4) and (4,5). The effect of the ground-level population density n_1 on Δn_{ij} is calculated. In this calculation, the atom-atom collision and the self-absorption of the resonance lines are taken into account. The n_1-dependence of Δn_{ij} remains almost constant until the self-absorption becomes significant. The threshold condition for laser oscillation is discussed in relation to the calculated Δn_{ij}. Laser oscillation is possible for the line pair (2,3) at an electron density and temperature higher than for the other pairs (3,4) and (4,5) when self-absorption is negligible. (21 refs.)

71690 'Pair correlations and internal energy of the two-dimensional Coulomb gas'. J.P.Hansen, P.Viot (Lab. de Phys. Theorique des Liquides, Univ. Pierre et Marie Curie, Paris, France).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.155-8 (25 April 1983).
The authors examine the pair correlations and the thermodynamic properties of the classical two-component plasma in two dimensions within the Poisson-Boltzmann and HNC approximations. (10 refs.)

71691 Integral-equation method for electric microfield distributions. C.A.Iglesias (Dept. of Phys., Univ. of Florida, Gainesville, FL, USA).
Phys. Rev. A (USA), vol.27, no.5, p.2705-9 (May 1983).
The Fourier transform of the electric microfield distribution function is expressed, without approximations, in terms of a two-body function. The two-body function may be interpreted as a 'generalized' radial distribution function and therefore is amenable to integral-equation techniques. In particular, the formalism is shown to simplify considerably in the hypernetted-chain approximation. (16 refs.)

52.25F Transport properties

71692 Plasma—Particle momentum and heat transfer: modelling and measurements. M.Vardelle, A.Vardelle, P.Fauchais (Univ. de Limoges, Limoges, France), M.I.Boulos.
AIChE J. (USA), vol.29, no.2, p.236-43 (March 1983).
Measurements were made of the two-dimensional flow and temperature field in a DC plasma jet under different operating conditions. The particle velocity and the in-flight particle temperature were also measured for narrow cuts of alumina powders, of mean particle diameters of 18, 23, 39 and 46 μm, injected in the jet. The results are compared with the predictions of a one-dimensional mathematical model. The measured and computed particle velocities are in good agreement. This is, however, not the case for the particle temperature where considerable differences are observed. An attempt is made to determine the parameters which are often unduly neglected in modelling work and to identify the areas where further work is needed. (18 refs.)

71693 Stochastic current driven by a wave. Xia Meng-fen (Inst. of Theoretical Phys., Peking Univ., Peking, China).
Acta Phys. Sin. (China), vol.32, no.3, p.338-45 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
A new mechanism of current driven by a wave is discussed. There is a series of resonant regions in the velocity space of a magnetized plasma interacting with a single wave. When the amplitude of the wave is higher than a threshold, some of the resonant regions will overlap each other and the stochastic effect will appear. If the overlapping region is asymmetric in the longitudinal velocity distribution of the electrons, the plasma current may be driven by the wave as a result of the stochastic effect. (11 refs.)

71694 On the conductance theory of plasmas. W.D.Kraeft, J.Blumlein, T.Meyer (Sektion Phys./Elektronik, Ernst-Moritz-Arndt-Univ., Greifswald, Germany).
Beitr. Plasma Phys. (Germany), vol.23, no.1, p.9-24 (1983).
In the framework of the linear response theory a quantumstatistical expression for the conductivity of nonideal plasmas is derived. In a simple approximation the influence of electron-ion scattering and that of masses of equal magnitude on the conductivity is discussed; the latter is expressed in terms of transport collision frequencies. (35 refs.)

71695 Retardation length of charged particlese in a high temperature plasma. S.V.Bozhokin, E.A.Choban.
Fiz. Plazmy (USSR), vol.9, no.2, p.412-19 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
Energy losses of charged particles in a high temperature plasma are calculated using dielectric penetration in a random phase approximation in which effects of degeneracy of the electron subsystem are significant. An expression is derived for the retardation length of a test particle, in which a correction to the Coulomb logarithm is taken into account, dependent on the velocity of the test particle. The retardation length of protons, tritons and alpha-particles are calculated for braking in high temperature plasma taking into account degeneracy of the electron subsystem. It is shown that for plasma with a temperature of O-0.5 keV and a density of $n \sim 10^{13}$-10^{24} cm^{-3} previous results for the retardation length are too low by ~3-5 times. (24 refs.) *A.G.C.*

71696 Electrical conductivity for radio-frequency fields in strongly magnetized plasmas with density fluctuations. Yu.S.Sayasov, Ch.P.Ritz (Dept. of Phys., Univ. of Fribourg, Fribourg, Switzerland).
J. Plasma Phys. (GB), vol.29, pt.2, p.299-315 (April 1983).
A general investigation of the electrical conductivity for radio-frequency (RF) fields in strongly magnetized plasmas with small-scale density fluctuations is performed within the cold plasma hydrodynamical approximation. It is shown that in such plasmas an RF phenomenon similar to the Bohm diffusion exists: the presence of stochastic RF electric field in a turbulent plasma can lead to a strong enhancement of the RF currents flowing in the direction of the applied electric field components transverse to the magnetic field. The appearance of these turbulent drift currents favours energy transfer from the RF fields to the plasma and thus leads to their stronger damping. This effect allows the authors to interpret quantitatively the enhanced damping of the magnetosonic waves observed in several experiments. The magnetized radially inhomogeneous cylindrical plasmas in these experiments are characterized by density fluctuations due to drift instabilities. The theory has also a number of other applications; an example is given of the whistlers damped by the ionospheric density fluctuations. (21 refs.)

71697 General solution of the Clemmow equation in a three-dimensional cold plasma, with a zero-velocity stream. J.Blandin, R.Pons, J.Skinazi (Phys. Theorique des Plasmas, Univ. Pierre et Marie Curie, Paris, France), G.Marcilhacy.
Lett. Nuovo Cimento (Italy), vol.37, ser.2, no.2, p.33-8 (14 May 1983).
The authors derive explicitly the general solution of Clemmow's electron reduced velocity equation (1974) for wave propagation of extremely large amplitude in a cold collisionless two-component plasma. (6 refs.)

71698 Doppler shift and ion mobility measurements of ArH^+ in a He DC glow discharge by infrared laser spectroscopy. N.N.Haese, Fu-Shih Pan, T.Oka (Dept. of Chem., Univ. of Chicago, Chicago, IL, USA).
Phys. Rev. Lett. (USA), vol.50, no.20, p.1575-8 (16 May 1983).
A new, infrared-laser-spectroscopic method for in situ ion drift-velocity and mobility measurements in a DC glow discharge is reported, a method sensitive to quantum effects in the ion transport process. Excellent agreement with earlier drift-tube studies for the mobility of ArH^+ in He is obtained. While no ion rotational energy dependence was observed in preliminary measurements, a vibrational dependence was suggested. (22 refs.)

71699 Magnetic field line reconnection experiments. W.Gekelman, R.L.Stenzel, N.Wild (Dept. of Phys., Univ. of California, Los Angeles, CA, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.277-87 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
A laboratory experiment concerned with the basic physics of magnetic field line reconnection is discussed. Stimulated by important processes in space plasmas and anomalous transport in fusion plasmas the work addresses the following topics: dynamic magnetic fields in a high beta plasma, magnetic turbulence, plasma dynamics and energy transport. First, the formation of magnetic neutral sheets, tearing and island coalescence are shown. Nonstationary magnetic fluctuations are statistically evaluated displaying the correlation tensor $\langle \mathbf{BB} \rangle$ in the ω-$\mathbf{k}$ domain for mode identification. Then, the plasma properties are analyzed with particular emphasis on transport processes. Although the classical fluid flow across the separatrix can be observed, the fluctuation processes strongly modify the plasma dynamics. Direct measurements of the fluid force density and ion acceleration indicate the presence of an anomalous scattering process characterized by an effective scattering tensor ν^*. Turbulence also enhances the plasma resistivity η^* by one to two orders of magnitude. (60 refs.)

71700 Experiments with pure electron plasmas. J.H.Malmberg, C.F.Driscoll, W.D.White (Dept. of Phys., Univ. of California, San Diego, La Jolla, CA, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.288-92 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
Pure electron plasmas are one of the simplest systems on which plasma wave and transport effects can be studied. Two recent experiments on this system are discussed. The loss of electrons due to anomalous transport has been measured over a six order of magnitude variation in containment time. The containment time scales approximately as $[\text{magnetic field/plasma length}]^2$. The growth of the $l=1$ diocotron wave due to resistance between sections of the bounding wall has been observed. The measured growth rates agree with theory. (15 refs.)

71701 Lower hybrid current derive and sustainment in WT-2 Tokamak. S.Tanaka, Y.Terumichi (Dept. of Phys., Faculty of Sci., Kyoto Univ., Kyoto, Japan).
Phys. Scr. (Sweden), vol.T2, no.2, p.423-7 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
The lower hybrid current drive experiments have been carried out in the WT-2 Tokamak. The RF power P_{rf} is injected near the end of Tokamak discharge by the four waveguides array. The plasma can be sustained by the RF driven current only during the RF injection period. The scaling of the RF driven current and the density limit are studied. The scaling of I_{rf} is obtained as $n_e \times I_{rf}/P_{rf} \simeq 0.15 \times 10^{13}$ $kA.cm^{-3}.kW^{-1}$. The density limit exists and it depends on the energy distribution of electrons in the ohmically heated initial plasmas. The maximum value obtained in the present experiments is 1.4×10^{13} cm^{-3}. The high frequency instability associated with the RF driven current has been studied and found it can be stabilized by the electron cyclotron heating. (10 refs.)

52.25P Emission, absorption, and scattering of radiation

71702 The infrared emission spectrum of an argon plasma jet between 4 and 25 microns. G.Winkelmann, J.Tilgner (Zentralinst. fur Phys. Chem., Akad. der Wissenschaften, Berlin, Germany).
Beitr. Plasma Phys. (Germany), vol.23, no.2, p.193-9 (1983). In German.
The infrared emission spectrum of an argon plasma jet was investigated in the wavelength range from 4 to 25 microns by means of a Fourier-transform spectrometer. Besides numerous sharp emission lines of argon (FWHH=1 cm^{-1}) several broad intensity maxima are observed at 4.636 μm, 7.435 μm and 12.346 μm with a FWHH of 7; 20 and 39 cm^{-1}. (11 refs.)

71703 An efficient numerical method for time-dependent NLTE radiation transfer. D.J.Bond (Blackett Lab., Imperial Coll. of Sci., & Technol., London, England).
J. Quant. Spectrosc. & Radiat. Transfer (GB), vol.29, no.5, p.429-34 (May 1983).
The author presents a numerical method for performing coupled time-dependent radiation transfer and atomic rate equation calculations. The method incorporates the desirable features of time-independent, non-local thermodynamic equilibrium (NLTE) radiation transfer calculations. It has the advantage that it allows existing time-independent calculations to be adapted to model time dependent effects. The approximations which are used are discussed. Calculations have been performed for a highly ionised silicon plasma with a single optically thick line. The line is taken to have a top-hat profile which is independent of position. Although the model is simple, it serves to illustrate some important features of time-dependent calculations. (9 refs.)

71704 Bremsstrahlung emission in a non LTE plasma. M.Lamoureux, C.Moller, P.Jaegle (Lab. de Spectroscopie Atomique et Ionique, Univ. Paris-Sud, Orsay, France).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.297-8 (9 May 1983).
The authors point out the great extent to which the calculated electron Bremsstrahlung emission departs from the LTE behaviour in the critical density region of a laser produced plasma. Consequences on the validity of a standard temperature diagnostic are discussed. (6 refs.)

71705 Plasma shifts of the Lyman lines to shorter wavelengths in C VI. J.C.Adcock,Jr., H.R.Griem (Lab. for Plasma, Univ. of Maryland, College Park, MD, USA).
Phys. Rev. Lett. (USA), vol.50, no.18, p.1369-72 (2 May 1983).
Blue shifts of ~85-60 mÅ have been observed for the first five members of the C VI Lyman series emitted from a laser-produced plasma plume at an electron density near 10^{21} cm^{-3}. These shifts are much larger than density-dependent effects associated with electron collisions and inhomogeneities in ion-produced electric microfields and opposite to plasma polarization shifts according to the linearized Debye model. A nonlinear Debye-type model is consistent with the measurements. (17 refs.)

71706 High-resolution X-ray spectra from molybdenum ions in the Alcator-*C* Tokamak. E.Kallne, J.Kallne (Harvard-Smithsonian Astrophys. Obs., Cambridge, MA, USA), R.D.Cowan.
Phys. Rev. A (USA), vol.27, no.5, p.2682-97 (May 1983).
The authors report on measurements of the X-ray line emission in the wavelength region $\lambda=4.3$-5.3 Å from molybdenum in charge states between 28+ and 32+. The experimental results were compared with calculated line spectra (also presented) which facilitated the identification of many of the principal $2p$-$3d$, $2s$-$3p$, and $2p$-$3s$ transitions. Some indications of weaker satellite-line contributions were also found. The principal $2p$-$3d$ transitions were found to be the dominant ones. In particular, Mo^{32+} gave stronger contributions than other charge states for our plasma condition of $T_e=1.0$-1.5 keV while available calculations of relative ion abundances have predicted Mo^{32+} to be relatively strongest at $T_e=2.5$-3.0 keV. (22 refs.)

71707 Multiply charged plasma-point ions. Yu.A.Bykovskii, G.A.Sheroziya.
Sov. Phys.-JETP (USA), vol.56, no.2, p.304-9 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.554-63 (Aug. 1982). [received: May 1983]
The singularities of the emission of multiply charged ions with charges up to $z=25$ from high-temperature 'plasma points' of a low-inductance spark are investigated. The existing theoretical premises concerning the nature of plasma points are analyzed. (23 refs.)

52.30 PLASMA FLOW; MAGNETOHYDRODYNAMICS

(see also 47.65 Fluid dynamics)

71708 On the averaged forces in bounded plasma in parallel electric and magnetic fields. N.A.Nikolov, P.N.Malinov, A.B.Yanovsky (Dept. of Phys., Sofia Univ., Sofia, Bulgaria).
Beitr. Plasma Phys. (Germany), vol.23, no.2, p.95-103 (1983).
Averaged forces of Miller's type, acting on the particles of a bounded plasma in parallel external AC electric and DC magnetic fields, are found on the basis of the equations of the two-component MHD. It is assumed, that standing transverse waves are excited in the plasma by the external source before the AC electric field is switched on. (16 refs.)

71709 The study of transverse magnetic field interaction with a two-phase low-temperature plasma flow. M.V.Zake, Ya.O.Shints, I.N.Yatchenko.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.75-83 (1983). In Russian.
The experimental investigation results of the transverse magnetic field interaction with low-temperature argon plasma containing aluminium particles are presented. Non-stationary heating, as well as evaporation and condensation of metal particles were studied. Gas dynamics and heat physics characteristics of plasma flow components were found to be greatly affected by the magnetic field magnitude. Thus, at $B<0.6$ T, the mean dimensions of a condensate increase whereas they have a pronounced decrease at $B>0.6$ T. (9 refs.)

71710 On the plasma-vacuum condition in the energy principle of Bernstein et al.. C.Lo Surdo (Centro Richerche Energia Frascati, Frascati, Roma, Italy).
Lett. Nuovo Cimento (Italy), vol.36, ser.2, no.18, p.600-2 (30 April 1983).
Discusses the plasma-vacuum condition in the well-known energy principle for fluidomagnetic stability problems by Bernstein et al. (1958). (13 refs.)

71711 Resistive MHD processes. D.Biskamp (Max-Planck-Inst. fur Plasmaphys., Garching, Germany).
Phys. Scr. (Sweden), vol.T2, no.2, p.405-9 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
The problem of fast magnetic reconnection across an x-type magnetic neutral point is reconsidered. Several different numerical computations of the 2D incompressible MHD equations are presented concerning externally driven as well as spontaneous reconnection. The common result of these computations is that in the limit of small resistivity reconnection occurs in a diffusion layer of finite length, corresponding to the Sweet-Parker reconnection model. A Petschek type process is only obtained by assuming a strongly enhanced resistivity in the diffusion region. (12 refs.)

52.35 WAVES, OSCILLATIONS, AND INSTABILITIES IN PLASMA

71712 Nonlinear theory of the instability of a modulated electron beam of low density in a plasma. I. Conservation laws of energy and momentum for electromagnetic waves in a nonequilibrium dispersive and dissipative medium in the case of a slow change of amplitude and phase of the wave. K.J.G.Kruscha (Sekt. Phys./Elektronik, Univ. Greifswald, Greifswald, Germany), A.N.Kondratenko.
Beitr. Plasma Phys. (Germany), vol.23, no.2, p.105-15 (1983).
A formula is given for the energy and momentum conservation laws for a narrow spectrum of electromagnetic waves in an unstable dispersive and dissipative medium by any level of dissipation and on condition that the amplitude and phase change slowly in the time and space period of oscillations. It is shown that the density of energy and momentum of the motion of resonant particles, connected with the propagation of the electromagnetic wave, generally cannot be expressed by the dielectric function of the unstable system. For example it is demonstrated that the well known Landau formula for determining the density of the wave energy in an unstable monoenergetic beam-plasma system in general is not applicable as it is often done in literature. (32 refs.)

71713 The stability of the relativistic Alfven waves. C.D.Ciubotariu, D.I.Zoler, N.S.Thirer (Dept. of Phys., Polytech. Inst. of Jassy, Jassy, Rumania).
Beitr. Plasma Phys. (Germany), vol.23, no.2, p.117-32 (1983).
Within the framework of the special relativity, the system of reference comoving with Alfven wave is defined and the form of the perturbations with respect to this system are deduced. The system of equations corresponding to the interaction of the waves, in the case when the relativistic Alfven wave can generate new Alfven waves and magnetosonic waves, is obtained in the most general form. In the one-dimensional case the time dependent perturbation method is used to obtain the dispersion equation for the relativistic coupled waves (decay processes). Finally, by solving numerically the dimensionless dispersion equation, the instability domains of the Alfven waves are obtained. It is shown that there are possible decay processes and modulational instabilities. (11 refs.)

71714 Polarizational instability of an extraordinary wave close to the electron cyclotron resonance. S.A.Bel'kov, V.N.Tsytovich.
Fiz. Plazmy (USSR), vol.9, no.2, p.240-9 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The nonlinear evolution of an extraordinary wave in a region near the electron cyclotron resonance is investigated. Equations are derived which describe the nonlinear variation of polarization, and solutions for monochromatic waves are studied. It is shown that the equations possess three different solutions, which correspond to three polarization waves, all of which are unstable. A quasistationary magnetic field is excited as a result of the development of the polarization instability. (15 refs.) *A.G.C.*

71715 The interaction of Rieman waves in a two-stream system and the nonlinear stage of a two-beam instability. A.V.Pashchenko.
Fiz. Plazmy (USSR), vol.9, no.2, p.264-72 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
A solution is found for a problem concerning the interaction of Rieman waves in a two-stream hydrodynamic system. The result is used to study the strongly nonlinear stage of a two-beam instability in a beam-plasma system when the densities of beam and plasma are comparable. The boundary of the instability at the hydrodynamic stage of the development, which occurs due to pumping of energy from one wave instability to another is described analytically. The amplitudes of all the variable quantities and the nonlinear growth rate vary with distance. The fine structure of the relationship of the amplitude to distance associated with the nonlinear action of a precursor to the propagating wave is investigated. (10 refs.) *A.G.C.*

71716 Electromagnetic solitons with trapped particles in an ion-beam plasma. I.V.Bachin, V.B.Krasovitskii.
Fiz. Plazmy (USSR), vol.9, no.2, p.278-81 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
It is shown that the propagation of solitons of electromagnetic (helical) fields along an ion beam in a plasma is accompanied by the capture of electrons with velocities close to the group velocity of the wave. The reverse effect of the trapped particles leads to the appearance of nonlinear dispersion of plasma and a reduction of the phase velocity of the wave in the region of propagation of field pulses. An optimum value for the density of the trapped electrons exists for which reduction of the phase velocity is synchronized with the braking of the ion beam and the field amplitude considerably exceeds the value for free solitons. This effect is considered as a possible mechanism for the acceleration of electrons along the magnetic field of the near-Earth plasma penetrated by means of solar protons. (3 refs.) *A.G.C.*

71717 Nonlinear stabilization of one-dimensional short wave modulation instability. B.N.Breizman, V.M.Malkin.
Fiz. Plazmy (USSR), vol.9, no.2, p.288-99 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The nonlinear stage of the modulation instability of wide spectra Langmuir turbulence is examined for conditions when the energy of the Langmuir waves is close to the instability threshold and the spatial scale of the growing disturbances are comaprable with the characteristic wavelength of plasmons. Equations are derived which describe the growth of the instability in a small nonlinearity approximation, and conditions for bringing about soft and hard nonlinear stabilization regimes are indicated. (10 refs.) *A.G.C.*

71718 Electrostatic modes in a magnetized plasma with a longitudinal density gradient. J.E.Maggs, G.J.Morales (Phys. Dept., Univ. of California, Los Angeles, CA, USA).
J. Plasma Phys. (GB), vol.29, pt.2, p.177-94 (April 1983).
An analytic study is made of the electrostatic mode structures which exist between the upper-hybrid cut-off and the plasma resonance in a plasma in which the zero-order density gradient points along the magnetic field. In general the solutions consist of long-wavelength cold modes which are converted to short-wavelength Bohm-Gross modes near plasma resonance. However, there exist certain discrete angles of propagation at which finite solutions exist that can be described solely in terms of cold plasma theory. The relevance of these processes to resonant absorption experiments in the auroral ionosphere is considered. A brief study is made of the changes produced by a finite angle between the density gradient and the magnetic field. The possibility of finding analogous low-frequency structures is also investigated. (5 refs.)

71719 On reflexion and trapping of upper-hybrid waves. E.Mjolhus (Inst. of Math. & Phys. Sci., Univ. of Tromso, Tromso, Norway).
J. Plasma Phys. (GB), vol.29, pt.2, p.195-215 (April 1983).
The theme of the paper is the relation between the so-called Z mode and the upper-hybrid wave in a magnetized plasma. First, certain problems as to reflexion and transmission of upper-hybrid waves at quasi cut-off (that is, cut-off predicted within electrostatic approximation) are stated and solved by singular perturbation technique. Then the theory is extended to a problem concerning generation and trapping of upper-hybrid waves in magnetic field aligned electron density irregularities. First a single density depression is considered, and then the formalism is further extended to a system of many parallel density depressions. The study was motivated by problems in the theory of artificial small-scale ionospheric irregularities occurring in radio wave experiments. (9 refs.)

71720 Magnetosonic wave propagation in the mode conversion regime. Y.Lapierre (EURATOM-CEA sur la Fusion, Fontenay-aux-Roses, France).
J. Plasma Phys. (GB), vol.29, pt.2, p.223-41 (April 1983).
The propagation of the fast magnetosonic wave is studied, taking into account the effect of the two-ion hybrid layer. Using a one-dimensional model, which includes density and magnetic field gradients, the wave equation is solved in the cold plasma approximation. The existence of radial eigenmodes confined between the two-ion hybrid layer and the low field side wall is predicted. Comparison with experimental data obtained on the TFR Tokamak confirms the theoretical conclusions. Toroidal eigenmodes are observed even in the mode conversion regime when the antenna is on the low magnetic field side. (22 refs.)

71721 The effect of microscale random Alfven waves on the propagation of large-scale Alfven waves. T.Namikawa, H.Hamabata (Dept. of Phys., Faculty of Sci., Osaka City Univ., Osaka, Japan).
J. Plasma Phys. (GB), vol.29, pt.2, p.243-53 (April 1983).
The ponderomotive force generated by random Alfven waves in a collisionless plasma is evaluated taking into account mean magnetic and velocity shear and is expressed as a series involving spatial derivatives of mean magnetic and velocity fields whose coefficients are associated with the helicity spectrum function of random velocity field. The effect of microscale random Alfven waves through ponderomotive and mean electromotive forces generated by them on the propagation of large-scale Alfven waves is also investigated. (11 refs.)

71722 Nonlinear interaction of waves in sharply bounded plasmas. T.Lindgren (Dept. of Plasma Phys., Umea Univ., Umea, Sweden).
J. Plasma Phys. (GB), vol.29, pt.2, p.255-73 (April 1983).
The author considers the nonlinear interaction of three high-frequency waves and low-frequency density perturbations in a sharply bounded plasma. The coupled equations are presented in a general and convenient form. To demonstrate the usefulness of the author's method explicit expressions are derived for the threshold of a number of possible instabilities in semi-finite and cylindrical plasmas. (29 refs.)

71723 Notes on the stability problem for inhomogeneous equilibria. K.R.Symon (Los Alamos Nat. Lab., Los Alamos, NM, USA).
J. Plasma Phys. (GB), vol.29, pt.2, p.275-86 (April 1983).
Several conclusions regarding the stability of inhomogeneous Vlasov equilibria are drawn from earlier work. A technique is presented for generating first-

order formulae for the change $\delta\omega$ in the frequency of any normal mode, when a parameter λ characterizing the equilibrium is changed slightly. Several applications are given, including a first-order calculation of the growth rate or damping of an electromagnetic mode due to the presence of plasma. A condition is derived for the existence of a normal mode with real frequency. When there are ignorable co-ordinates, the normal modes can be written in the form of waves propagating in the ignorable directions. The character of the modes depends on certain symmetries in the dynamic spectral matrix. Special cases arise when the orbits can be approximated in certain ways. (5 refs.)

71724 The thermal self-focusing of a wave beam in an under dense plasma. I. The wave spectrum. M.J.Giles (School of Math. & Phys. Sci., Univ. of Sussex, Brighton, England).
J. Plasma Phys. (GB), vol.29, pt.2, p.325-58 (April 1983).
The present series of papers is concerned with the problem of the thermal self-focusing of an electromagnetic wave in an underdense plasma which is examined within the context of ionospheric modification by high-power radio waves. The author formulates this problem as a coherent four-wave interaction between a pump wave, Stokes side-band waves and a thermally driven density perturbation. The treatment assumes that the heating of the electrons in the interference pattern of the pump and side-band waves is in equilibrium with longitudinal heat conduction and energy transfer to the ions and, in addition, that the density perturbation is subject to decay on account of longitudinal ambipolar diffusion, ambient plasma drift motion, recombination and the stabilizing influence of perturbations to the electrical conductivity. The author deals with the linear theory of the instability with a view to determining the effect of a finite beam width. The author attacks this problem by considering the response of the plasma-beam system to a small localized source, obtaining a response function which is evaluated asymptotically for large times. The author concentrates on the finite beam width in the direction perpendicular to the axis in the plane of the axis and the magnetic field. The author therefore includes the component of the drift parallel to this plane but ignores the component perpendicular to it, which is considered later. (15 refs.)

71725 Experimental determination of the velocity and width of plane ion-acoustic solitons propagating in a plasma. T.Pierre, G.Bonhomme, J.R.Cussenot, G.Leclert (Lab. de Phys. des Milieux Ionises, Faculte des Sci., Vandoeuvre les Nancy, France).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.159-61 (25 April 1983).
The velocity and width of plane ion-acoustic solitons propagating in a plasma have been studied experimentally. The measurement of their amplitude is made by analysis of the 'instantaneous' probe characteristics in the soliton. The results agree with the KdV theory, in contrast with previous works. (13 refs.)

71726 Coherence and threshold of current-driven potential relaxation instability. R.Schrittwieser (Phys. Dept., Univ. of California, Irvine, CA, USA).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.162-4 (25 April 1983).
It is shown that the coherence of the current-driven potential relaxation instability decreases with the plasma density whereas the threshold increases. (14 refs.)

71727 Parametric excitation of the drift wave by a modulated ion beam. M.Yatsuzuka, K.Satoh, S.Nobuhara (Dept. of Electrical Engng., Himeji Inst. of Technol., Himeji, Japan), K.Yatsui, M.Yokoyama.
Phys. Lett. A (Netherlands), vol.95A, no.6, p.293-6 (9 May 1983).
Parametric excitation of the drift wave is observed by an ion beam modulated near the lower-hybrid frequency. An RF field parallel to the magnetic field is found to play an important role in the excitation of the instability. Substantial increase of the ion and electron temperatures is observed. (10 refs.)

71728 Runaway-current sustainment by lower-hybrid waves. L.Muschietti, K.Appert, J.Vaclavik (Centre de Recherches en Phys. des Plasmas Assoc. EURATOM, Ecole Polytech. Federale de Lausanne, Lausanne, Switzerland).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1532 (9 May 1983).
Recently Liu et al. (vol.48, p.1479, 1982) has proposed a theory to explain the low-density current-derived experiments, in which they have assumed a steady state too prematurely. In contrast to the runaway case (see Muschietti et al., vol.25, p.1187, 1982) there is indeed no DC electric field to accelerate the electrons in the region $[v_c, v_D]$. Because of that Liu et al. had to assume that the distribution function displays a negative slope there; thus they may balance the backward flux due to collisions with the quasilinear diffusion by the plasma waves. However, this assumption is inconsistent with the pitch-angle diffusion by the anomalous Doppler effect which happens in the adjacent region $v>v_D$ and must manifest itself in the region $[v_c,v_D]$ by the advent of a positive slope. Since the equations used in the model are the same as in the authors' quasilinear code they have tested the model numerically. They found that, for a realistic range of parameters, the preformed runaway tail cannot be maintained and the current carriers relax toward the bulk of the electron distribution. Thus, the authors claim that the Liu et al.'s model is inconsistent with their equations. (2 refs.)

71729 Current drive experiments on the PLT Tokamak. F.Jobes, S.Bernabei, P.Efthimion, W.Hooke, J.Hosea, E.Mazzucato, E.Meservey, R.Motley, J.Stevens, S.von Goeler (Plasma Phys. Lab., Princeton Univ., Princeton, NJ, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.418-22 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
Lower hybrid current-drive experiments have been carried out on the PLT Tokamak. Steady currents up to 175 kA have been maintained for three seconds and 400 kA for 0.3 s by the RF power alone. The principal current carrier appears to be a high energy (~100 keV) electron tail, concentrated in the central 20-40 cm diameter core of the 80 cm PLT discharge. Effective current drive is observed only for $\bar{n}_e \leq 8\times10^{12}$ cm^{-3}. This limitation may be a wave propagation phenomenon and not a fundamental plasma physics effect. (5 refs.)

71730 Early history. E.Teller (Lawrence Livermore Nat. Lab., Univ. of California, Livermore, CA, USA).
In book: *Fusion. Vol.1. Magnetic confinement. Part A*, E.Teller [Ed.], p.1-29. London, England: Academic Press (1981), xiii+491 pp. [0 12 685201 4]
The author gives the historical background to fusion. He explains the reasons for the basic similarity as well as the great difference between the rapid development of thermonuclear explosions and the difficult research on thermonuclear reactors. He discusses controlled fusion in low-density plasmas and types of magnetic fusion machines as well as plasma properties and the role of instabilities. (4 refs.)

71731 Tokamak plasma stability. M.N.Rosenbluth, P.H.Rutherford.
In book: *Fusion. Vol.1. Magnetic confinement. Part A*, E.Teller [Ed.], p.31-121. London, England: Academic Press (1981), xiii+491 pp. [0 12 685201 4]
The authors point out the central role which the control of instabilities play in the problem of magnetically controlled fusion. Their discussion on stability consists of a general look at thermodynamic considerations pertinent to the stability of magnetically confined plasmas, and a categorisation of the principal types of instability in both open and closed confinment systems. The authors have emphasised the Tokamak because its axial symmetry renders it most amenable to theoretical treatment and because it is now the leading reactor contender.

52.35R Plasma turbulence

71732 Anomalously high absorption and anomalously strong scattering in a turbulent laser plasma. V.Yu.Bychenkov, V.P.Silin.
Fiz. Plazmy (USSR), vol.9, no.2, p.282-7 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
Basic theories of ion-acoustic absorption and scattering of laser radiation are formulated with the help of angular scattering found for ion-acoustic fluctuations and of generalized Kadomtsev-Petviashvili spectra. It is shown that the interaction of electromagnetic radiation with an ion beam can lead to anomalously large absorption and scattering of radiation. (9 refs.) *A.G.C.*

71733 Computer simulation of plasma turbulence in open systems. Yu.S.Sigov (Keldysh Inst. of Appl. Maths., Acad. of Sci., Moscow, USSR).
Phys. Scr. (Sweden), vol.T2, no.2, p.367-79 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
A short review of the results of kinetic simulation of collective phenomena in open plasma systems with the variable total energy and number of particles, i.e. the particle and energy fluxes on boundary surfaces and/or their internal sources and channels is given. Three specific problems are considered in different detail for such systems in one-dimensional geometry: the generation and evolution of double layers in a currently unstable plasma; the collisionless relaxation of strongly non-equilibrium electron distributions; the Langmuir collapse and strong electrostatic turbulence in systems with parametric excitation of a plasma by an external pumping wave and with cooling the fast non-Maxwell electrons. In all these cases the non-linearity and a collective character of processes give examples of new dissipative plasma structures that essentially widen ideas about the nature of the plasma turbulence in non-homogeneous open systems. (40 refs.)

71734 On the transition to turbulence in magneto-hydrodynamic models of confined plasmas. E.K.Maschke, B.Saramito (Dept. de Recherches sur la Fusion Controlee, CEN, Fontenay-aux-Roses, France).
Phys. Scr. (Sweden), vol.T2, no.2, p.410-17 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
Starting from a model of an interchange-unstable plasma in a shearless magnetic field, the successive bifurcations and the transition to turbulence of the system are studied in various approximations. Numerical calculations using the finite element method and a spectral method with mode truncation yield converging results in certain domains of parameters. In the last part of the paper it is shown that a tearing-unstable plasma in a sheared magnetic field has a formally similar description and therefore should also be investigated in terms of bifurcation theory. 52.35T Shock waves

71735 Laser generation of strong shock waves. S.I.Anisimov, A.M.Prokhorov, V.E.Fortov (Lebedev Phys. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.63-9 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1081-9 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
After a brief survey of models for the equation of state, the authors give some simple estimates of the pressures in shock waves generated by laser pulses and discuss the roles of various factors that distort the ideal setting of the shock-wave experiments. These factors include rear and lateral decompression waves, which cause a deviation from the steady state in the shock wave, non-Maxwellian electrons and X-rays, which heat the target before the arrival of the shock wave, and transport and relaxation processes, which determine the generation time for the steady state shock wave. The authors derive the optimum working conditions and estimate the laser energy needed to obtain a given pressure. The final part of the survey deals with diagnosis in laser shock-wave experiments. 52.40 PLASMA INTERACTIONS

52.40D Electromagnetic wave propagation in plasma

71736 The ponderomotive force and magnetic field generation effects resulting from the non-linear interaction between plasma-wave and particles. He Xian-tu (Inst. of Atomic Energy, Acad. Sinica, Beijing, China).
Acta Phys. Sin. (China), vol.32, no.3, p.325-37 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
Starting from Vlasov-Maxwell equations by using the method of self-consistent field theory, the author sets up first the coupling relation between distribution function and density of low-frequency oscillating particles and high-frequency EF, low-frequency MF in Fourier representation. Then, in the time-space representation, a set of equations for the nonlinear interaction including the effects of magnetic field generation, ponderomotive force and Landau damping are derived through the expansion of the low-frequency linear dielectric function under various approximations. Finally, also the author gives the Lagrangian density and conserved quantities and discusses briefly whether the magnetic field can promote the formation of soliton in three dimensions. (11 refs.)

71737 Diffraction of electromagnetic waves on a metal ball surrounded by a spherically symmetric uniform plasma layer taking into account the spacial dispersion. N.A.Azarenkov, V.P.Olefir, I.Kh.Peneva.
Bulg. J. Phys. (Bulgaria), vol.10, no.1, p.98-107 (1983).
The penetration of a plane electromagnetic wave in a spherically symmetric uniform plasma layer surrounding a metal ball has been considered. The amplitudes of the secondary fields in the high-and low-frequency ranges have been calculated. The spectra of own multipole resonance vibrations, defined by the thermal electron motion, have been obtained. (10 refs.)

71738 Parametric instability of waves with an inhomogeneous pumping wave field in an inhomogeneous plasma. A.A.Andreev.
Fiz. Plazmy (USSR), vol.9, no.2, p.231-3 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The problem of the interaction of waves in a plasma when pumping wave and plasma are inhomogeneous with respect to various coordinates as occurs for example when a laser beam propagates in an inhomogeneous plasma, is examined. From a system of full equations shortened versions are derived which are examined in a resonance decay region. The amplification coefficient obtained is similar to that obtained by other authors. (6 refs.) *A.G.C.*

71739 Collisionless electron acceleration in the interaction of a microwave field with a dense isotropic nonuniform plasma. I.R.Gekker.
Fiz. Plazmy (USSR), vol.9, no.2, p.234-9 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
An analysis is presented of experimental data from the interaction of microwaves with a dense strongly nonuniform isotropic plasma in a waveguide, with a range of variation of E of from 1 to 10^4 v/cm. It is shown that calculated threshold values of the fields for parametric instability in a nonuniform plasma considerably exceed the thresholds recorded for accelerated electrons, which prevents the detection of electron instability thresholds. Comparison of experimental data indicates agreement with theoretical ideas concerning the resonance mechanism of electron acceleration. (19 refs.) *A.G.C.*

71740 The 'super-reflection' effect during the interaction of high power radiation with moving plasma. N.E.Andreev, K.Baumhertel, O.M.Gradov, K.Zauer, D.Zunder.
Fiz. Plazmy (USSR), vol.9, no.2, p.254-63 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The conditions for producing a 'super-reflection' effect, both analytically within the framework of a simple model of the evolution of the plasma density profile, and using self-consistent numerical methods for the deformation of plasma density by the ponderomotive force, are investigated. (10 refs.) *A.G.C.*

71741 Whistler-mode propagation at frequencies near the electron gyrofrequency. S.S.Sazhin (Phys. Inst., State Univ. Leningrad, Leningrad, USSR).
J. Plasma Phys. (GB), vol.29, pt.2, p.217-22 (April 1983).
Parallel whistler-mode propagation in a hot anisotropic plasma at frequencies near the electron gyrofrequency is considered by using analytical methods and a simple graphical technique, without any special restrictions on the value of the imaginary part of the plasma dispersion function argument. An exact criterion for the possibility of whistler-mode propagation in the vicinity of the electron gyrofrequency is derived. In particular it is pointed out that whistlers in this frequency interval can propagate only in a very hot and rarefied plasma submerged in a strong magnetic field. These whistlers can only be damped, the modulus of the decrement of the damping cannot exceed 1.1 times the electron plasma frequency. The refractive index remains close to unity. (10 refs.)

71742 Magnetic-field generation by a finite-radius electromagnetic beam. O.M.Gradov (P.N. Lebedev Phys. Inst., Moscow, USSR), L.Stenflo.
Phys. Lett. A (Netherlands), vol.95A, no.5, p.233-4 (2 May 1983).
The authors point out that magnetic fields can be generated in a plasma because of the inhomogeneity in the radial intensity distribution of a linearly polarized electromagnetic beam. (4 refs.)

71743 Damping of large-amplitude plasma waves propagating perpendicular to the magnetic field. J.M.Dawson, V.K.Decyk, R.W.Huff, I.Jechart, T.Katsouleas, J.N.Leboeuf, B.Lembege, R.M.Martinez, Y.Ohsawa, S.T.Ratliff (Dept. of Phys., Univ. of California, Los Angeles, CA, USA).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1455-8 (9 May 1983).
Computer simulations of magnetosonic waves, velocity-shell instabilities, and upper hybrid heating show evidence of a general damping mechanism for large-amplitude electrostatic waves propagating perpendicular to a magnetic field: Particles trapped by a wave of frequency ω and phase velocity V_{ph} see an electric field $V_{ph}\times B$, which accelerates them parallel to the wave front until the $\nu\times B$ force is large enough for detrapping. For $\omega\gg\omega_c$, velocities as large as $(\omega/4\omega_c)V_{ph}$ can be attained, within a time $\omega_c t\approx\omega/4\omega_c$. (8 refs.)

71744 Aspects of the physics of laser-plasma interactions. T.J.M.Boyd (Univ. of Wales, Bangor, Wales).
Phys. Scr. (Sweden), vol.T2, no.2, p.310-23 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
A variety of topics in laser-plasma interaction physics are reviewed. The trend from exploding-pusher experiments to ablative compression studies already evident at the time of the Nagoya Conference in 1980 has gathered momentum. The particular emphasis placed at present on the scaling of interaction phenomena with wavelength, in particular stimulated Raman scattering and two-plasmon decay, filamentation and jet formation together with aspects of absorption and transport phenomena is essential for a proper understanding of laser-plasma interactions. (83 refs.)

71745 Intense laser self-focusing in plasmas. Xu Zhizhan, P.H.Y.Lee, Xu Yuguang, Zhang Wenqi, Wang Lijun (Shanghai Inst. of Optics & Fine Mech., Acad. Sinica, Shanghai, China).
Sci. Sin. (China), vol.26, no.4, p.435-41 (April 1983).
Strong evidence for self-focusing or filamentation of a laser beam in plasmas is found from time-integrated 1-D spatially resolved spectra and 2-D spatially resolved images of the second harmonic emission from 1.06 μm laser-plasma interactions. The authors also present preliminary results of investigation of factors such as target *Z* and prepulse which affect self-focusing or filamentation. (14 refs.)

71746 Radiation resistance of corner-driven loop antenna immersed in a two component warm plasma. A.Kumar, R.K.Gupta (Dept. of Phys., Malaviya Regional Engng. Coll., Jaipur, India).
Curr. Sci. (India), vol.52, no.5, p.214-125 (5 March 1983).
Loop aerials of different types are widely used for satellite communications and rocket-probe studies in the ionosphere. They are simple in construction, and more efficient than conventional dipoles of similar dimensions. The radiation characteristics of corner-driven loop antenna have not yet been studied in two component warm plasma. The purpose of the note is to compare the theoretical values of the radiation resistance of the corner-driven loop with the experimental observations of the loop used on Ariel-3 satellite and the theoretical results from an Alford loop aerial in an electron-ion warm plasma. 71747 Dynamics of heavy particles close to a negatively charged wall in a dense fully ionized plasma. A.V.Zharinov, Yu.V.Sanochkin.
Fiz. Plazmy (USSR), vol.9, no.2, p.397-400 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The distribution of densities and balance of heavy particles in a bounded layer formed during the contact of dense cold fully-ionized plasma with a negatively charged wall are examined. The breakdown time of the pre-electrode layer in the presence of cathode sputtering and vaporization of the surface of the walls is estimated. (5 refs.) *A.G.C.*

71748 Detailed spectra of high-power broadband microwave emission from intense electron-beam-plasma interactions. K.G.Kato, G.Benford, D.Tzach (Dept. of Phys., Univ. of California, Irvine, CA, USA).
Phys. Rev. Lett. (USA), vol.50, no.20, p.1587-90 (16 May 1983).
For a relativistic electron beam penetrating an unmagnetised plasma, a change is seen in the emission spectrum from $\omega\sim\omega_p, 2\omega_p$ line emission to

continuous $\omega \gg \omega_p$ emission, as $n_b/n_p \rightarrow 1$. High-power (of order megawatts per gigahertz) broadband radiation up to ~100 GHz suggests collective Compton-boosting mechanisms in a new regime of super-strong turbulence. Highly directional emission and magnetic field dependence agree with this interpretation. (16 refs.)

71749 Plasma boundary layer in limiter and divertor Tokamaks. M.Keilhacker, K.Lackner, K.Behringer, H.Murmann, H.Niedermeyer (Max-Planck-Inst. fur Plasmaphys., Garching, Germany).
Phys. Scr. (Sweden), vol.T2, no.2, p.443-53 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
Experimental results and theoretical models for the boundary layer of toroidal confinement devices are described. Emphasis is put on the scrape-off layer of poloidal divertor Tokamaks which have demonstrated a significant reduction in impurity content as compared to limiter operation. The competition of transport processes parallel and perpendicular to the field lines, determining the profiles of plasma density, temperatures and impurity concentrations, is described. The role of hydrogen recycling in the divertor chamber is underlined, which decides the flow Mach number in the scrape off, the plasma parameters in the target plate vicinity and the regime of energy transport along the field lines. Limiter and divertor operation in ASDEX are compared and the favourable results of the latter explained by the reduced impurity production of target plates and their distance from closed field lines, which impurity ions would have to overcome by diffusion against the plasma flow into the divertor chamber. 71750 Evolution of a nonlinear stage of a beam instability of plasma in a magnetic field. G.D.Aburdzhaniya, I.M.Pankratov.
Fiz. Plazmy (USSR), vol.9, no.2, p.273-7 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The excitation of longitudinal oscillations of a plasma by a nonrelativistic spiral monoenergetic low density beam is investigated numerically in a single-mode approximation for the case when the wave propagates at an angle of about $\pi/2$ to the magnetic field. It is shown that during the growth of the instability a qualitative change in the form of the phase density of the particles of the beam is possible. (5 refs.) *A.G.C.*

71751 Nonlinear stabilization of a collisionless radial divergence of a relativistic electron beam in a plasma. V.G.Dorofeenko, V.B.Krasovitskii.
Fiz. Plazmy (USSR), vol.9, no.2, p.357-65 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
A study is reported of the defocusing effect of Cerenkov and cyclotron modes on a relativistic beam of electrons moving in a plasma long an external magnetic field. The role of nonlinear effects in conditions of collective scattering of resonance electrons on plasma oscillations is explained and possible mechanisms of nonlinear stabilization of the instability are indicated. Nonlinear saturation of the Cerenkov mode takes place even in weak magnetic fields due to the reduction in growth rate with increase in amplitude of oscillations in the beam. The cyclotron (anomalous Doppler) mode is stabilized by the effect of nonlinear dispersion in a plasma accompanied by detuning of the phase resonance of the beam with the wave. In both cases the oscillation amplitudes of the radius of the beam and the field are found. (5 refs.) *A.G.C.*

71752 Plasma heating by rotating relativistic electron beams. P.I.John (Phys. Res. Lab., Ahmedabad, India).
Phys. Scr. (Sweden), vol.T2, no.2, p.298-302 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
Experimental observations on the interaction of intense electron beams with magnetically confined plasmas, when the beam has a substantial component of the velocity in the direction perpendicular to the magnetic field are summarised. The interaction takes place in two stages; in the first stage the response is essentially magnetic due to return currents induced in the plasma, and in the second stage, those currents decay converting energy into plasma heating. Observation of fast magnetic field diffusion points to beam-induced turbulence in the plasma. (10 refs.)

71753 Physics of REB-plasma interaction. A.V.Arzhannikov, A.V.Burdakov, V.S.Koidan, L.N.Vyacheslavov (Inst. of Nuclear Phys., Novosibirsk, USSR).
Phys. Scr. (Sweden), vol.T2, no.2, p.303-9 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
The results of the experimental study of the REB-plasma interaction in the two-stream instability regime are presented. The distribution function of plasma electrons has been studied with the use of the laser scattering system, soft X-ray diagnostics and a multifoil analyzer of fast electrons. It is shown that during an effective REB-plasma interaction the distribution function of heated electrons is strongly non-equilibrium. A high-energy part of the distribution function has been registered in the experiments simultaneously by three independent methods. The density of 'hot' electrons with a characteristic energy of about 1 keV constitutes several per cent of the total plasma density. The experimental results obtained are discussed in terms of the two-stream instability of the REB in a plasma. (42 refs.)

52.50 PLASMA PRODUCTION AND HEATING

71754 Magnetoplasma lamination due to microwave gyroresonant heating. A.B.Shvartsburg (Izmiran, Troitsk, USSR).
Beitr. Plasma Phys. (Germany), vol.23, no.1, p.1-8 (1983).
The hysteresis transitions between two temperature states of a collisional magnetoplasma due to Joule heating near by the electron gyroresonance are analysed. The propagation of intense extra-ordinary gyroresonant microwave across the magnetic field in a plasma is responsible for such jump-like thermic effects, the wave amplitudes being less than the 'characteristic plasma field'. The transversal heat conductivity may lead to formation of spatially periodical temperature profiles in the hysteresis region of wave's intensity; the spatial periods of such profiles are much less than the Joule dissipation length of heating wave. The thermodiffusion, stimulated by temperature lamination, may form the spatial oscillations of magneto-plasma density across the magnetic field. (6 refs.)

71755 Distortion of the distribution function of weakly RF heated minority ions in a Tokamak plasma. D.Anderson (Inst. for Electromagnetic Field Theory, Chalmers Univ. of Technol., Goteborg, Sweden).
J. Plasma Phys. (GB), vol.29, pt.2, p.317-23 (April 1983).
An investigation is made of the effect of RF-induced velocity diffusion on the distribution function, $f(\mathbf{v})$, of the heated ion species in minority heating schemes using the fast Alfven wave. The solution for the distorted distribution function is expressed in a Legendre series from which deviations from isotropy can be assessed. Solutions are found in the limits of high and low velocities and the elongation of the constant $f(\mathbf{v})$ surfaces is also given. (2 refs.)

71756 Electron cyclotron heating of a Tokamak plasma. V.E.Golant (A.F. Ioffe Phys.-Tech. Inst., Leningrad, USSR).
Phys. Scr. (Sweden), vol.T2, no.2, p.428-34 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
Contains the analysis of the state of electron cyclotron resonance heating in Tokamaks. It presents the results of numerical simulation of ECRH at different conditions and the review of last experiments performed on Tokamaks T-10, FT-1, JFT-2 and JSX-B. The opportunities and constraints of ECRH in Tokamaks are discussed. (25 refs.)

52.50J Plasma production and heating by laser beams

71757 Breakdown in air near a solid target in a CO_2 laser beam. V.I.Konov (Lebedev Phys. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.31-7 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1044-51 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
To determine which type of plasma is observed in an experiment and the corresponding mechanism for interaction between the radiation and the target, it is necessary particularly to define the fundamental differences between the two types of laser plasma. Naturally, if the target is irradiated in a sufficiently high vacuum, breakdown in the adjacent layers of residual gas is impossible, and therefore the observed plasma is also always a vapor jet. A much more complicated situation arises when the target is irradiated in a gas, including air, at pressures not too widely different from normal, where one can get either a vapor jet or a gas breakdown plasma in accordance with the conditions. It is therefore very important to devise criteria that define the type of plasma reliably; although low-threshold gas breakdown near the target was observed comparatively long ago, the literature often speaks only of plasma formation generally or else that air breakdown is observed near the target without indicating a sufficient basis for this. The author used a pulsed TEA CO_2 laser in the spectroscopic studies. (18 refs.)

71758 Pulse heating of a metal by a laser plasma in a subsonic air flow. V.P.Ageev, A.A.Gorbunov, V.I.Konov, P.I.Nikitin, A.S.Silenok, N.I.Chapliev (Lebedev Phys. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.43-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1058-64 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
When the irradiation spot is small, most of the energy absorbed by the target in laser breakdown enters parts of the surface fairly remote from the energy release medium. This is explainable in terms of concepts from explosions. A region of hot gas or hot sphere (HS) is formed when the explosion products and the air entrained by the shock wave expand to atmospheric pressure P_0. The HS localizes much of the energy, but the size may substantially exceed that of the deposition zone. The authors consider the time and mechanism of the energy transfer from the HS formed by low-threshold gas breakdown near a solid surface. (9 refs.)

71759 Slow burning of a laser plasma. I.A.Bufetov, A.M.Prokhorov, V.B.Fedorov, V.K.Fomin.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.114-21 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1141-9 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
A brief survey is made of papers on the slow burning of a laser plasma. Detailed consideration is given to experiments on discharge propagation in the slow-burning mode along the beam of a neodymium laser in atmospheric air. Gas motion has been observed in front of and behind the discharge front. The threshold conditions have been examined for plasma propagation in the laser beam and absorption of the laser radiation in the discharge. (41 refs.)

71760 Spectral study of a carbon laser plasma expanding into a background medium. O.B.Anan'in, Yu.A.Bykovskii, B.V.Zamyshlyaev, A.G.Guz', E.L.Stupitskii, A.M.Khudoverdyan.
Fiz. Plazmy (USSR), vol.9, no.2, p.319-25 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The results of an investigation into the space-time characteristics of the separate charges of the ion component of a carbon laser plasma (CII,CIII) during its expansion into a rarefied background medium (air) in a pressure range of from 10^{-3} to 10^{-1} torr are reported. The diagnostic method used was time-of-flight spectrometry of the line radiation from the laser plasma formed on a carbon target. The relationship of the space and time distribution of ions with respect to distance from the target and the background pressure is shown. Results are presented of a theoretical analysis of the mechanism of the interaction of a laser plasma with the background medium, which leads to a process of energy transfer to the background medium. Results of the calculations are compatible with experiments. (6 refs.) *A.G.C.*

71761 The interaction of carbon dioxide laser radiation with a pulsed vacuum arc. T.P.Hughes, M.A.El-Farra (Dept. of Phys., Univ. of Essex, Colchester, England).
J. Phys. D (GB), vol.16, no.5, p.811-28 (14 May 1983).
A pulsed, channelled vacuum arc is described which produces reproducible carbon plasmas with $N_e \sim 1.5 \times 10^{18}$ cm^{-3} and $T_e \sim 4.5$ eV. Spectroscopic measurements in the VUV and visible regions have been used to determine accurately the distributions of N_e and T_e in time and space. The absorption of CO_2 laser pulses at irradiances up to 2×10^9 W cm^{-2} by the plasma has been measured and for small absorbed energies is in good agreement with the predictions of inverse bremsstrahlung theory. The electron temperature in the plasma rose by over 5 eV when strong absorption occurred, resulting in a smaller absorption for the later part of the laser pulse and a delay in the peak of the transmitted pulse. A weak cylindrical blast wave was generated whose propagation was followed spectroscopically. (21 refs.)

71762 Observation of Stark-shifts of Lyman-α lines of low-Z ions in laser-produced plasmas. S.Hashimoto (Dept. of Phys., Tokai Univ., Kanagawa, Japan), N.Yamaguchi.
Phys. Lett. A (Netherlands), vol.95A, no.6, p.299-302 (9 May 1983).
Red-shifts have been observed for Lyman-α lines of $Z=4$-7 ions at an electron density of 10^{21} cm^{-3}. The plasma was produced by a 0.1 TW 100 ps glass laser. The shift was measured relative to the line center of the spatially resolved unperturbed line. The results are compared with theory. (21 refs.)

71763 Features of lateral energy transport in CO_2-laser-irradiated microdisk targets. D.M.Villeneuve, G.D.Enright, M.C.Richardson (Div. of Phys., Nat. Res. Council of Canada, Ottawa, Ontario, Canada).
Phys. Rev. A (USA), vol.27, no.5, p.2656-62 (May 1983).
Calorimetric investigations of the lateral flow of energy away from CO_2-laser-irradiated regions of disk targets are reported. The fraction of energy reaching the rear surface is shown to decrease with increasing target diameter, but does not depend on target thickness. Most of the plasma blow-off energy in front of the target is due to fast ions, but these account for less than 20% of the rear blow-off energy. The rear surface is heated preferentially at the edges, in the plane of laser polarization. These observations are consistent with energy being transported laterally by hot electrons inside the corona which expands at a speed of $\sim 10^8$ cm/s. (25 refs.)

52.50L Plasma production and heating by shock wave and wire explosion

71764 Ignition of a laser target by a focused shock wave. V.A.Shcherbakov.
Fiz. Plazmy (USSR), vol.9, no.2, p.409-11 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
Some aspects of the problem of thermonuclear ignition by a focused shock wave and heating of a previously compressed spherical target is examined. In particular for a target of a mass $m \approx 400$ μg of DT_3 mixture (for a target with a DT density $p_o = 0.1$g/cm^3 the initial radius $r_0 = 1$ mm) previously compressed to a density for 40 g/cm^3, the compression velocity μ necessary for its ignition by a focused shock wave $\approx (1.5$-$1.6) \times 10^7$ cm/sec; the deposition of energy in the target at the ignition point is $E \approx 30$ kJ, and the thermonuclear energy released during heating (for a freely moving target) $Q \approx 50$ MJ, so that the coefficient of thermonuclear amplification $k = Q/E_{las} \approx 1600$ (since only a small part ~10% of the laser energy is transferred to the target, the ratio of thermonuclear energy to laser energy will be of course, considerably less). (6 refs.) *A.G.C.*

52.55 PLASMA EQUILIBRIUM AND CONFINEMENT

71765 Electrostatic corrections to the electron magnetic-drift waves. Zhang Yang-zhung (Southwestern Inst. of Phys., Sichuan, China).
Chin. Phys. (USA), vol.3, no.1, p.21-2 (Jan.-March 1983). [received: May 1983]
An explanation is given for the apparent anomalous behavior of electron transport in the Tokamak experiment while ion transport appears to be classical. (5 refs.)

71766 Determination of the runaway-electron distribution function by cyclotron absorption in a Tokamak. A.V.Zvonkov, E.V.Suvorov, A.V.Timofeev, A.A.Fraiman.
Fiz. Plazmy (USSR), vol.9, no.2, p.314-18 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
It is shown that in a weakly relativistic region the runaway electron distribution function in Tokamak can be determined by measurements of the coefficient of absorption of electron cyclotron oscillations. Probing of the plasma should be carried out in the vertical direction. (13 refs.) *A.G.C.*

71767 Internal helical instabilities in a Tokamak with anisotropic plasma. A.B.Mikhailovskii.
Fiz. Plazmy (USSR), vol.9, no.2, p.326-35 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
A theoretical study is presented of internal helical instabilities in a Tokamak with anisotropic plasma, which is of interest in connection with the injection into Tokamak of a beam of fast neutral atoms and the use of HF-heating of plasma. Stability criteria are derived for the first mode ($m=1$), and for higher modes $m>1$. It is shown that anisotropy is most significant for disturbances with $m=1$, and that for $m=1$ it can lead to a specific anisotropic helical instability. The effect of high plasma pressure on this instability is examined, and it is shown that it is stabilized if the average pressure of the plasma is large compared with the average pressure of the poloidal magnetic field. (9 refs.) *A.G.C.*

71768 Plasma heating experiments at the second harmonic of the electron cyclotron resonance in the T-10 Tokamak. V.V.Alikaev, L.I.Agapov, Yu.I.Arsen'ev, A.B.Berliozov.
Fiz. Plazmy (USSR), vol.9, no.2, p.336-42 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
Results are presented of a study of plasma heating in Tokamak T-10 at the second harmonic of the electron cyclotron resonance. During the introduction of microwave power of mixed polarization, an increase in the electron temperature at the centre of the plasma column $\simeq 500$eV is obtained. The heating efficiency is 50-60% in regimes with power being introduced of $P \simeq 500$kW and electron densities of $\bar{n}_e \simeq 3 \times 10^{13}$ cm^{-3}. The absence or the very weak dependence of electron thermal conductivity on T_e is demonstrated. (6 refs.) *A.G.C.*

71769 Magnetic system of the TO-2 Tokamak with divertor. L.I.Artemenkov, A.P.Popryadukin, A.N.Chudnovskii.
Fiz. Plazmy (USSR), vol.9, no.2, p.343-50 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The results of a study of the vacuum magnetic field of the TO-2 racetrack Tokamak with two toroidal divertors located in the straight sections are reported. The geometric characteristics of the TO-2 Tokamak are presented, and results of calculations of the parameters of the magnetic system, the location of the separatrix, the characteristics of the divertor, and other matters are discussed. Calculated characteristics are compared with experimentally measured values obtained by a method using the transmission of an electron beam in argon and are found to be in agreement. (4 refs.) *A.G.C.*

71770 Ideal MHD ballooning modes in toroidal magnetic traps with shear. A.B.Mikhailovskii, V.V.Demchenko, A.Ya.Omel'chenko.
Fiz. Plazmy (USSR), vol.9, no.2, p.351-6 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
A formalism is developed which allows ballooning modes in a wide class of equilibrium toroidal magnetic configurations with shear to be studied, among which are Tokamaks with arbitrary transverse cross-section shape, closed traps with a spatial magnetic axis and various equilibrium stellarators with helical windings. The stability criteria for ballooning modes in the simplest traps with spatial magnetic axis is a helical column. It is shown that for a given plasma pressure a certain value of shear exists for which the ballooning mode is less dangerous than disturbances of the Mercier type. (13 refs.) *A.G.C.*

71771 Radiative amplification of reversed field diffusion in a neutral layer during the formation of a compact toroid. V.N.Semenov, V.F.Strizhov.
Fiz. Plazmy (USSR), vol.9, no.2, p.401-8 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The dynamics of a current layer in a compact torus in the presence of impurities is examined. It is shown that intensive radiation losses in impurities can lead to rapid annihilation of counter-streaming magnetic fluxes in a time of the order of that observed in the experiments. Maximum permissible concentrations of carbon impurity in the discharge and the flow rate of plasma in the current layer are estimated for various parameters of the discharge. (6 refs.) *A.G.C.*

71772 Transverse ion losses in end stoppers of an ambipolar trap. L.S.Pekker.
Fiz. Plazmy (USSR), vol.9, no.2, p.420-33 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
Transverse losses of 'central' ions trapped in the end stoppers of an ambipolar trap are examined. These losses are associated with a marked elongation of the drift trajectory in the transverse direction and can significantly decrease the containment time of the plasma in the trap. A classification of the drift envelopes of trapped ions is presented, and the flux of these ions at the diaphragm is calculated. The influence of the 'reverse loss cone' instability is discussed, and also the effect of the radial electric field on plasma containment time. (17 refs.) *A.G.C.*

71773 Plasma formation in a gas-liner pinch. K.H.Finken, U.Ackermann (Inst fur Experimentalphys. V, Ruhr-Univ. Bochum, Bochum, Germany).
J. Phys. D (GB), vol.16, no.5, p.773-81 (14 May 1983).
A gas-liner pinch is optimised for Stark broadening investigations. To obtain the desired discharge conditions the gas injection, the preionisation and geometrical aspects of the discharge chamber are analysed. Quantitative agreement is found between the observed plasma compression and a 'snowplough' model. The density distribution of the compressed plasma column is derived from double exposure holograms. The peak electron density $N_e \approx 10^{18}$ cm^{-3}; the temperature gives $kT_e \approx 10$ eV. (10 refs.)

71774 Observation of radial equilibrium and transition to a helix of a gas-embedded *Z* pinch. A.E.Dangor, M.B.Favre Dominguez, S.Lee, E.Kahan (Blackett Lab., Imperial Coll. of Sci. & Technol., London, England).
Phys. Rev. A (USA), vol.27, no.5, p.2751-4 (May 1983).
A laser-initiated, gas-embedded *Z* pinch is operated with a preheat current which adjusts the plasma parameters by Joule heating and expansion so that when the main current is injected, the plasma core is heated under conditions of pressure balance. This results in a pinch which has a constant radius during the time of current rise. The pinch is stable during this time and thereafter undergoes a rapid transformation into a radially expanding helical structure. The growth time and wavelength of the instability is in good agreement with the theoretical predictions of the $m=1$ magnetohydrodynamic instability. (10 refs.)

71775 Physics of non-neutral plasma. N.Rostoker, A.Fisher (Dept. of Phys., Univ. of California, Irvine, CA, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.293-7 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
The theoretical basis for magnetic confinement is examined. Recent progress on confinement of pure electron plasma involves magnetic mirrors and simple toroidal configurations. This progress is described. Non-neutral configurations involving electrons and ions in mirror geometry are investigated. A basic experiment on mirror stability is proposed. (17 refs.)

71776 Present and future toroidal confinement experiments at Princeton Plasma Physics Laboratory. H.P.Furth (Plasma Phys. Lab., James Forrestal Campus, Princeton, NJ, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.324-35 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
A broad program of research on the confinement of plasma in nested toroidal magnetic surfaces is being carried out at the Princeton Plasma Physics Laboratory. Tokamak research at PPPL is progressing into the phase of technology development, in preparation for the support of a large-scale reactor-oriented effort. World-wide experimental research has brought the stellarator concept to the point of plasma-physical demonstration; at PPPL, the theoretical study of reactor-compatible stellarator design is yielding promising new results. Initial spheromak formation experiments have been successful. The confinement properties of the spheromak will begin to be studied experimentally during the next year. (43 refs.)

71777 The physics of mirror systems. R.F.Post (Lawrence Livermore Nat. Lab., Univ. of California, Livermore, CA, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.336-46 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
In recent years the emphasis in research on the magnetic mirror approach to fusion has been shifted to address what are essentially economically-motivated issues. The introduction of the tandem mirror idea solved in principle the problem of low Q (low fusion power gain) of mirror-based fusion systems. In order to optimize the tandem mirror idea from an economic standpoint, some important improvements have been suggested. These improvements include the thermal barrier idea of Baldwin and Logan and the axicell concept of Kesner. These new modifications introduce some special physics considerations. Among these are: (1) the MHD stability properties of high energy electron components in the end cells; (2) the optimization of end-cell magnetic field configurations with the objective of minimizing equilibrium parallel currents; (3) the suppression of microstabilities by use of 'sloshing ion' distributions. Following a brief outline of tandem mirror concepts, the above three topics are discussed, with illustrative examples taken from earlier work or from recent design studies. (29 refs.)

71778 The physics of spheromak. G.C.Goldenbaum (Lab. for Plasma & Fusion Energy Studies, Univ. of Maryland, College Park, MD, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.359-66 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
The present state of understanding of spheromak physics is reviewed by comparing experimental results with MHD equilibrium and stability theory. (29 refs.)

71779 The physics of the dense Z-pinch in theory and in experiment with application to fusion reactor. M.G.Haines (Blackett Lab., Imperial Coll. of Sci. & Technol., London, England).
Phys. Scr. (Sweden), vol.T2, no.2, p.380-90 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
A new generation of *Z*-pinches employing high voltage, high current pulsed lines as power sources produce dense hot plasmas with enhanced stability properties. Three methods of *Z*-pinch formation are currently in use: (1) cylindrical collapse and compression of a pre-ionised gas; (2) laser initiation and Joule heating of a gas embedded pinch; and (3) hollow gas puff and subsequent collapse to the axis. The first method shows no dynamic bounce and no instability over about ten radial Alfven transit times. The laser initiated *Z*-pinch shows benign helical structures, whilst the gas puff experiments are known for their high X-ray energy conversion associated with $m=0$ instabilities. The first two experimental conditions are relevant for fusion. A calculation of energy balance for satisfying Lawson conditions with axial and radial energy losses and radiation loss shows that a current I of $\sim 10^6$ A and a line density N of 6×10^{18} m^{-1} are required. This leads to two coincidences of physical quantities that are very favourable for controlled fusion. (29 refs.)

71780 Stability and confinement of spheromaks and field reversed configurations. W.E.Quinn (Los Alamos Nat. Lab., Los Alamos, NM, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.391-8 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
The formation, confinement and stability of two types of compact toroids, spheromaks and field reversed configurations (FRC), are reviewed. Spheromaks, which contain both toroidal and poloidal magnetic fields, have been formed with magnetized coaxial plasma guns, by a combination of Z- and θ-pinch techniques and by an electrodeless slow induction technique, and trapped in both prolate and oblate flux conservers. As predicted by theory, the prolate configuration is unstable to the tilt mode, but the oblate configuration with a conducting wall is stable. Configuration lifetimes of up to 0.8 ms are observed. The FRC is a high-beta, highly prolate compact toroid formed with field-reversed theta-pinch techniques and having purely poloidal magnetic field. Theory predicts unstable fluting and internal tilting modes, but they are not observed experimentally. Configurations with high densities $\sim 10^{15}$ cm^{-3} and with lifetimes of 50-120 μs are terminated by an $n=2$ rotational mode of instability. (51 refs.)

71781 REB injected toroidal plasma. A.Mohri, K.Narihara, Y.Tomita, M.Hasegawa, T.Tsuzuki, T.Kobata (Inst. of Plasma Phys., Nagoya Univ., Nagoya, Japan).
Phys. Scr. (Sweden), vol.T2, no.2, p.399-404 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
A stable relativistic electron beam (REB) ring for plasma confinement was formed by REB injection with the help of image currents in a resistive shell, and then the ring was compressed in major radius by a factor 2.0. The current rise well obeyed the adiabatic scaling law. (13 refs.)

71782 Topics in reversed-field-pinch physics. H.Dreicer (Los Alamos Nat. Lab., Los Alamos, NM, USA).
Phys. Scr. (Sweden), vol.T2, no.2, p.435-42 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).
Laboratory observations made on the reversed-field pinch (RFP) show that this magnetic confinement configuration exhibits 'metastable' minimum energy properties similar to those predicted by Taylor. The theoretical basis of the RFP is reviewed and compared with recent observations made on the Los Alamos ZT-40 RFP device. Particular emphasis is placed on the observation that the reversed field is regenerated by a dynamo-like mechanism for times large compared to the classical field diffusion time. (37 refs.)

71783 The Tokamak. H.P.Furth (Princeton Plasma Phys. Lab., Princeton Univ., Princeton, NJ, USA).
In book: *Fusion. Vol.1. Magnetic confinement. Part A*, E.Teller [Ed.], p.123-242. London, England: Academic Press (1981), xiii+491 pp. [0 12 685201 4]
The author provides a brief overview of the Tokamak field and therefore an introduction to the technical literature. He covers Tokamak configuration and confinement, heating methods and MHD stability and future Tokamak devices. (263 refs.)

71784 Stellarators. J.L.Shohet (Torastron-Stellarator Lab., Univ. of Wisconsin, Madison, WI, USA).
In book: *Fusion. Vol.1. Magnetic confinement. Part A*, E.Teller [Ed.], p.243-89. London, England: Academic Press (1981), xiii+491 pp. [0 12 685201 4]
A stellarator is a toroidal magnetic confinement device in which plasma confinement is achieved by generating closed toroidal magnetic surfaces, much like those appearing in a Tokamak. Unlike the Tokamak, stellarators generate their confining surfaces entirely by means of currents flowing in external conductors. The author gives a general introduction to stellarators and their variations, such as torsatrons, heliotrons, figure-eights etc. Particle orbits, transport, equilibrium and stability for these configurations are discussed and some specific comments on the present-day status of experiments and a view of reactor implications are included. (62 refs.)

71785 Mirror theory. T.K.Fowler (Lawrence Livermore Nat. Lab., Univ. of California, Livermore, CA, USA).
In book: *Fusion. Vol.1. Magnetic confinement. Part A*, E.Teller [Ed.], p.291-355. London, England: Academic Press (1981), xiii+491 pp. [0 12 685201 4]
Magnetic mirror devices differ from Tokamaks in the shape of the magnet. All magnetic fusion approaches can be divided into two types. One is the toroidal or 'closed' type in which magnetic lines remain within the plasma volume; Tokamaks are toroidal. The other is the linear or 'open' type in which field lines escape out the ends. The plasma also escapes unless the ends are 'plugged' up by some means. Far the most successful means of end plugging has been the magnetic mirror effect. The author describes the basic mirror concept, both for its own interest and as a background for understanding the new ideas now unfolding, and the tandem mirror concept which derives naturally from it. He also mentions mirror stability theory, mirror reactors and the field-reversed mirror. (77 refs.)

71786 Experimental base of mirror-confinement physics. R.F.Post (Lawrence Livermore Nat. Lab., Univ. of California, Livermore, CA, USA).
In book: *Fusion. Vol.1. Magnetic confinement. Part A*, E.Teller [Ed.], p.357-435. London, England: Academic Press (1981), xiii+491 pp. [0 12 685201 4]
The author discusses some of the more important steps in the experimental work carried out to confine high-density plasmas at fusion temperatures. (59 refs.)

71787 The reversed-field pinch. D.A.Baker, W.E.Quinn (Los Alamos Nat. Lab., Univ. of California, Los Alamos, NM, USA).
In book: *Fusion. Vol.1. Magnetic confinement. Part A*, E.Teller [Ed.], p.437-475. London, England: Academic Press (1981), xiii+491 pp. [0 12 685201 4]
The pinch effect, which is the self-constriction that occurs in a plasma as a result of the passage of a unidirection current, is one method of plasma heating and confinement. The authors review the method of producing reversed field pinch (RFP) configurations, stability theory and RFP experiments. (123 refs.)

52.60 RELATIVISTIC PLASMA

71788 Longitudinal oscillations in a relativistic plasma. B.K.Shivamoggi (Dept. of Theoretical Phys., Australian Nat. Univ., Canberra, Australia).

Fizika (Yugoslavia), vol.15, no.1, p.83-92 (Jan.-March 1983).

Longitudinal oscillations in a relativistic plasma are studied. First a three-dimensional space+time approach (which is not manifestly covariant) is used. An approximate evaluation of the dispersion relation for the case of a weakly-relativistic plasma is then made. The problem of two-stream instability in a relativistic plasma is discussed, and the relativistic effects are shown to have a stabilising nature on the problem. Next, these treatments are repeated using a manifestly-covarient four dimensional space-time approach, and attention is drawn to discrepancies in the results deduced by these two approaches. (6 refs.)

71789 Action principle for a hot plasma in curved space-time. H.Heintzmann (Inst. fur Theoretische Phys., Univ. zu Koln, Koln, Germany), M.Novello.

Phys. Rev. A (USA), vol.27, no.5, p.2671-81 (May 1983).

A manifestly covariant extension of the Low-Sturrock Lagrangian is formulated and its invariance properties are investigated. In particular the authors clarify the meaning of particle displacements which play the role of the configuration variables of the variational principle in general relativity. As a consequence of the variational principle the authors derive a conservation law for Witham's (1970) wave-vector action in the WKB approximation. (30 refs.)

52.70 PLASMA DIAGNOSTIC TECHNIQUES AND INSTRUMENTATION

71790 Transportation of far-IR bemas for use in plasma diagnostics. M.R.Siegrist, I.Kjelberg, R.Behn (Centre de Recherches en Physique des Plasmas, Ecole Polytech. Federale de Lausanne, Lausanne, Switzerland).

Appl. Opt. (USA), vol.22, no.9, p.1318-24 (1 May 1983).

In this paper the authors discuss certain aspects concerning the transport and focusing of a high power far-IR laser beam into a plasma for Thomson scattering measurements. To attain the required megawatt power level in a D_2O laser, it is important to use efficiently the volume of the optically pumped vapor. The best known method to achieve this is use of an unstable resonator which produces a beam with an annular intensity profile. This has a negative effect on the quality of the focused beam and on the intensity profile incident on the beam dump. A system utilizing a Cassegrainian telescope and spatial filtering techniques is found to be a good solution. (9 refs.)

71791 Bringing JET on line [nuclear research]. R.Norton (Norsk Data Ltd., Newbury, England).

Comput. Syst. (GB), vol.3, no.5, p.41-5 (May 1983).

Describes the control and data acquisition system (CODAS), for the Joint European Torus nuclear fusion experiment. CODAS is based on a distributed system of 27 Norsk Data computers. (no refs.)

71792 Cooled spherical electrostatic probe with a thin collisionless layer. A.V.Norin.

Fiz. Plazmy (USSR), vol.9, no.2, p.300-7 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*

A theoretical model is proposed for calculating the volt-ampere characteristics of a quiescent cooled spherical probe operating in a regime when the mean free path length of charged particles exceeds the Debye radius but is considerably less than the dimensions of the probe. In the model all regions of the plasma are divided into two zones which require quantitatively different descriptions, a collisionless pre-zone layer and a diffusional zone. It is shown that with a reduction in the temperature of the probe the current in the probe is decresed. Relationships are constructed for the floating potential vs. temperature of the probe for an argon plasma. For saturation currents expressions are derived in analytic form which in the limiting case of a thermostatic probe in a continuous media transform into expressions derived from the continuum theory of Su and Lamb (1963). (9 refs.) *A.G.C.*

71793 Plasma density measurements in a fast linear theta-pinch by absolute intensity measurements of bremsstrahlung. V.A.Burtsev, B.V.Lyublin.

Fiz. Plazmy (USSR), vol.9, no.2, p.308-13 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*

A method is described for measuring the density of plasma by the absolute intensity of bremsstrahlung in the visible region of the spectrum. The technique of absolute calibration of the measuring apparatus is examined in detail, and estiamtes are made of the accuracy of the measurements. Results of determinations of the density of plasma in the 'UTRO' apparatus are reported. A radial profile of the density constructed by the method of Pierce is presented. Densities at the profile maximum are 10^{17} and 2.10^{17} cm^{-3} at initial pressures of 0.4 and 1.0 torr respectively. (9 refs.) *A.G.C.*

71794 Mobile probe for examining a dense plasma. V.N.Kovalev, A.A.Lyapin, M.M.Chursin.

Instrum. & Exp. Tech. (USA), vol.25, no.4, pt.2, p.979-81 (July-Aug. 1982). Translation of: *Prib. & Tekh. Eksp. (USSR)*, vol.25, no.4, p.180-1 (July-Aug. 1982). [received: May 1983]

A description is given of a mobile probe for diagnosing dense plasma that enables one to measure the distributions of the major parameters along the radius at each pass. The probe speed is 20-1000 mm/sec, the time spent in the plasma ranging from 20 msec to 2 sec. (2 refs.)

71795 Characteristics of a photodiode matrix for use with weak light fluxes. G.I.Aponin, A.A.Besshaposhnikov, V.B.Voronin, D.M.Kulakov, A.D.Petrova, N.V.Simonova.

Instrum. & Exp. Tech. (USA), vol.25, no.4, pt.2, p.981-4 (July-Aug. 1982). Translation of: *Prib. & Tekh. Eksp. (USSR)*, vol.25, no.4, p.182-4 (July-Aug. 1982). [received: May 1983]

The characteristics of an MIF-15 integrated MIS photodiode matrix are given in relation to the parameters of the optical radiation and the working conditions. The results indicate that the matrix can be used as a detector with weak light fluxes, in particular in recording the scattered radiation in research on plasma with an electron concentration $N=10^{16}$-10^{18} cm^{-3}. (5 refs.)

71796 Evidence of anomalous multiplet line shapes in optically thick, laser-produced plasmas. D.Santi, P.Nicolosi (Centro di Studio sui Gas Ionizzati, Univ. di Padova, Padova, Italy).

J. Quant. Spectrosc. & Radiat. Transfer (GB), vol.29, no.6, p.549-52 (June 1983).

Reports observations of anomalous line shapes for the transitions $2p$-$3d$ (^2P-^2D) emitted by the Li-like ions N(V), O(VI), F(VII) in laser-produced plasmas. These transitions are normally doublets but show completely different characteristics (e.g. triplet structures or inversion of two-component intensity ratios) in the plasmas. The observed line profiles are accounted for in terms of opacity and Doppler effect produced by plasma expansion. This interpretation is independent of the particular transition involved, i.e. multiplet structures can generate more complicated features with various unexpected new components, anomalous intensity ratios, etc. (7 refs.)

71797 Electron temperature measurement by Thomson scattering in Tokamak NOVA II. S.Masamune, I.Yokoyama, M.Fukao, H.Nishihara (Dept. of Nuclear Engng., Kyoto Univ., Kyoto, Japan).

Mem. Fac. Eng. Kyoto Univ. (Japan), vol.44, pt.4, p.451-9 (Oct. 1982). [received: May 1983]

The Thomson scattering method was applied to determine the temperature and density profiles of plasma electrons in the NOVA II Tokamak. The radial profile of electron density has been found to be approximately parabolic, while the temperature profile appeared more peaky and can be represented by the square of the parabolic expression. The electron energy confinement time determined by this method is in good agreement with that predicted by the Alcator scaling law. (10 refs.)

71798 Temperature measurement of an N_2 glow discharge by emission spectroscopy. A.Plain, A.Ricard (Lab. de Phys. des Gaz et des Plasmas, Univ. Paris-Sud, Orsay, France).

Phys. Lett. A (Netherlands), vol.95A, no.5, p.235-8 (2 May 1983).

The rotational temperature (T_R) of a cold N_2 glow discharge was deduced from the intensity distribution of the $N_2(^3\Pi_u, \nu'=0 \rightarrow B^3\Pi_g, \nu''=0)$ $\lambda=337.1$ nm R-branch. Likewise, the neutral temperature (T_g) was measured with a thermocouple located on the axis of the discharge. It is shown that $T_R=T_g$ for $300<T_g<700$K. (10 refs.)

71799 Plasma boundary diagnostics by laser induced fluorescence. E.Hintz (Inst. fur Plasmaphys., KFA Julich GmbH, Julich, Germany).

Phys. Scr. (Sweden), vol.T2, no.2, p.454-8 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).

For an efficient control of the effects of plasma surface interaction improved diagnostics of the plasma edge region is needed. Laser induced fluorescence offers the possibility to measure the density, the velocity distribution and the flux density of neutral and ionized particles with good time and space resolution. In contrast to currently used probes it does not disturb the plasma and is not affected by it. A survey on results obtained with this technique in Tokamaks and other magnetic confinement devices is presented. It is shown that fluxes of metal atoms emitted by the wall can be determined with good accuracy. In addition important information on processes of plasma surface interaction can be obtained. From the measured spatial distribution of particle densities the ionization length as well as T_e can be derived and knowledge about the structure of the scrape off layer is gained. Using laser induced fluorescence on injected beams of suitable chosen metal atoms, n_e and T_e can be determined in the boundary layer even at low n_e. Present limits of the method with respect to type and density of species to be detected and future prospects are discussed. (22 refs.)

71800 Density fluctuation measurement by infrared light scattering. D.Gresillon, C.Stern, A.Hemon, A.Truc, T.Lehner (Ecole Polytech., Palaiseau, France), J.Olivain, A.Quemeneur, F.Gervais, Y.Lapierre.

Phys. Scr. (Sweden), vol.T2, no.2, p.459-66 (1982). [received: April 1983] (1982 International Conference on Plasma Physics, Goteborg, Sweden, 9-15 June 1982).

Density fluctuation observation can be obtained by scattering of electromagnetic radiation. New developments and applications are presented. By heterodyne detection the scattered signal is shown to be the time variation of a space Fourier transform of the density. The antenna beam, that especially defines the sensitivity, is experimentally investigated. The time variation is used in two occurrences, to check quantum efficiency uniformity on detectors area, and in an air turbulence where the interspectrum is obtained between two scattering devices looking at different regions. Calibration formulas are given for quantitative measurement of density fluctuation spectrum. Observations are also reported on a Tokamak plasma on the drift wave spectrum, and on a new second order group of oscillations that were observed during ion cyclotron radiofrequency heating. The analysis shows this new group is a forced oscillation by beating of the drift waves with the high-frequency heating wave, and its amplitude provides a measurement of the HF wave electric field. 52.75 PLASMA DEVICES AND APPLICATIONS

(see also 28.52 Fusion reactors, 86.30L Electrogasdynamic and magnetohydrodynamic conversion; for ion sources, see 29.25 Particle sources and targets)

71801 **Investigations of the turbulent flow field in a high-speed plasma jet enclosed in a vessel.** E.Hayess (Zentralinst. fur Elektronenphys., Akad der Wissenschaften, Institutsteil IV, Berlin, Germany).
Beitr. Plasma Phys. (Germany), vol.23, no.2, p.133-44 (1983). In German.
The spatial distribution of temperature and velocity in a turbulent plasma jet enclosed in a large diameter tubular vessel has been measured with thermocouple probes and dynamic pressure probes and corrected by an iterative computation method. The results show that the behaviour of the plasma jet in principle is not different from the behaviour of an ordinary gas jet or a flame. Due to the mass entrainment from surroundings, the jet is divergent and died out very rapidly. On account of conservation of mass, the author expects a retrograde motion of the gas at the wall of the tubular vessel. Because the corresponding velocity is very small it falls below the detection limit of the measurement system. (31 refs.)

71802 **Plasma technologies for powder particles.** E.Kranz (Tech. Hochschule Ilmenau, Ilmenau, Germany).
Elektrie (Germany), vol.37, no.3, p.142-4 (1983). In German.
A survey of principles, properties, and applications of plasma spraying and powder transformation and generation in plasma is given, together with grain size transformation, powder particle formation, power reduction, and melting. They are effected within the power range of 10^3 to 10^7 W, mostly in plasma reactors. The product application is made in nuclear engineering for hard material production, reflector surfaces, filters, fillers, pigments, phase stabilization, metallurgy, and semiconductor techniques, and is of great industrial importance. (2 refs.)

71803 **State of the plasma cutting in GDR.** H.Forster, P.Wiese.
Elektrie (Germany), vol.37, no.3, p.149-54 (1983). In German.
Plasma cutting equipment with the power range of 3 to 100 kW have been developed in the GDR. These equipments are working in production at home and abroad. Metallic materials up to 150 mm in thickness may be cut by machine or by hand. Especially, the great cutting velocities are of advantage, making possible the coupling with the most modern directing machines. Examples are discussed in detail, showing how the light, noise and damaging material loads appearing during plasma cutting may be reduced to unobjectionable values through protective measures. (11 refs.)

71804 **Two-dimensional plasma model for the arc-driven rail gun.** J.D.Powell (Ballistic Res. Lab., USA ARRADCOM, Aberdeen Proving Ground, MD, USA), J.H.Batteh.
J. Appl. Phys. (USA), vol.54, no.5, p.2242-54 (May 1983).
A previously developed one-dimensional model for studying the fluid-mechanical electrodynamical properties of the plasma in an arc-driven rail gun is extended to two dimensions. The analysis includes deriving a set of general, time-dependent equations, the solution of which yields the associated properties of the arc. These equations are then solved under the assumptions that the flow variables are steady in a frame of reference which accelerates with the arc, and that the effect of the arc's acceleration upon these variables can be neglected. Numerical calculations are carried out to analyze arcs in recent experiments. In addition to the numerical calculations, some approximate analytic solutions, which are applicable under certain limiting conditions, are also worked out. These limiting-case solutions are then used to derive a set of scaling relations which indicate how the arc properties vary with gun size, projectile mass, and acceleration characteristics. Considerable discussion of the assumptions and the results is given emphasizing particularly the physical reasons for the differences with previous one-dimensional calculations. (18 refs.)

71805 **Efficiency and erosion characteristics of plasma jet igniters.** P.R.Smy (Faculty of Engng., Univ. of Alberta, Edmonton, Alberta, Canada), R.M.Clements, J.D.Dale, D.Simeoni, D.R.Topham.
J. Phys. D (GB), vol.16, no.5, p.783-91 (14 May 1983).
The rate of erosion of both ceramic and metal in a typical plasma jet igniter has been monitored as a function of various experimental parameters. Even under the most favorable conditions it appears that working lifetimes may be limited to the order of ten hours—a figure in line with previous measurements of arc erosion. Direct measurements of the thermal energy delivered by the igniter to the adjacent gas reveal that overall efficiencies $\sim 10\%$ are attained. In order to minimise erosion while maintaining a given delivery of thermal energy it is found essential to work with low initial voltages on the energy storage capacitor. (12 refs.)

71806 **Interaction of finely dispersed particles with the column of a constricted arc.** S.P.Polyakov (Dnepropetrovsk Metall. Inst., Dnepropetrovsk, Ukrainian SSR).
J. Eng. Phys. (USA), vol.43, no.2, p.933-5 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.303-6 (Aug. 1982). [received: April 1983]
It is shown that when particles of powder interact with the column of a constricted arc, in a plasmotron nozzle channel, repulsive forces are created. (6 refs.)

71807 **High-power narrowband millimeter waves generated by the electron beam emitted from the plasma focus.** K.Schmitt, H.Krompholz, F.Ruhl, G.Herziger (Inst. fur Angewandte Phys., Tech. Hochschule Darmstadt, Darmstadt, Germany).
Phys. Lett. A (Netherlands), vol.95A, no.5, p.239-41 (2 May 1983).
High-power narrowband millimeter-wave pulses ($P \approx 1$ MW, $\Delta f/f < 5 \times 10^{-2}$, duration <600 ps) have been observed at a 1.6 kJ plasma focus. The microwaves are generated in the frequency range 30 GHz$<f<$120 GHz by a periodic train of electron bunches emitted from the plasma. The power of the harmonics $2f$ and $3f$ indicates width of the electron bunches below 4 ps and a maximum diameter of the beam of 1 mm. (7 refs.)

71808 **Plasma cutting.** K.A.Bunting (Electricity Council Res. Centre, Capenhurst, England).
Colloquium on New Tools for Industrial Processes, London, England, 14 April 1983 (London, England: IEE 1983), 1 pp.
Summary form only given. Discusses the development of a supersonic, non-transferred, d.c. plasma jet. The commercial rationale for its development is briefly discussed. There are two main types of plasma jet which can be used for cutting, these are compared. The cut speed in any material is determined by the power density incident upon the material, the jet or beam diameter and the thermal properties of the material. A relationshp and families of curves derived from it for copper and iron are presented. It is shown that high power densities are required in order to be able to cut metal foils without distortion. 71809 **Characteristics of a transferred-arc plasma.** M.T.Mehmetoglu, W.H.Gauvin (McGill Univ., Montreal, Quebec, Canada).
AIChE J. (USA), vol.29, no.2, p.207-15 (March 1983).
The basic characteristics of a transferred arc argon plasma were determined using a cathode assembly suitable for transferring the electric arc to a molten metal bath or to a cooled anode. They indicated that the sustained voltage depended strongly on the arc length and much less on current. The inlet gas velocity past the cathode tip was determined to be an important operating parameter, rather than the volumetric gas flowrate. The measurement of the axial and radial profiles of temperature was effected with $\pm 8\%$ accuracy by a novel diagnostic technique. Temperatures up to 18500K were observed on the axis of the plasma column, near the cathode tip, and decayed in both radial and axial directions. A sweeping microprobe was used to measure the axial and radial profiles of velocity. Velocities up to 190 m/s were recorded. The presence of a relatively colder flow surrounding the plasma column was detected. Mass and energy balances performed by taking this flow into account agreed with the measured input rates. (32 refs.)

71810 **Explosive electron emission and formation of a cathode spot in pulsed volume discharges.** S.A.Genkin, Yu.D.Korolev, G.A.Mesyats, A.P.Khuzeev.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.84-7 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1306-9 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Investigation of the conversion of a pulsed volume discharge of enhanced pressure into a spark discharge has established that in most cases the transition occurs in two stages: first a cathode spot forms, and then a high-conductivity channel develops from the spot. The authors demonstrate the relationship between the modes of combustion of the discharge in the volume phase and the behavior of the cathode spot. They indentify regions of parameters of the volume discharge with respect to the field strength in the column and the current density, which manifests effects associated with the specific behavior of the spot (current cutoff, propagation of spots over cathode surface, regular arrangement of spots). They study the volume discharge in nitrogen at a pressure of 100 mm Hg, with the voltage on the gap below the breakdown value, was initiated by a beam of fast electrons with a duration of 100 nsec. (9 refs.)

71811 **Experimental investigations of axial pressure gradients in low-pressure discharges at high current.** W.Ebert (Phys.-Tech. Inst., Akad. der Wissenschaften, Jena, Germany).
Beitr. Plasma Phys. (Germany), vol.23, no.2, p.153-63 (1983). In German.
Measurements of the axial pressure in low-pressure discharges at high currents have been carried out. It was possible to show, that the axial pressure in the discharge tube is mainly determined by the volume of the cathode-bulb or the anode-bulb volume and not by the discharge current or the filling pressure. For the case, that the volume of the anode-bulb was very large in comparison with the cathode-bulb, the pressure in the discharge tube was nearly constant (grad $p \approx 0$). The results of these experiments are in agreement with numerical calculations. (6 refs.)

71812 **Formation of AC discharges between glass insulated electrodes in Ne+1% N_2 mixtures. I. Experiments and analysis.** W.Stern (Akad. der Wissenschaften, Gasentladungsphys., Greifswald, Germany), H.Lange.
Beitr. Plasma Phys. (Germany), vol.23, no.2, p.165-80 (1983).
AC plasma displays made use of medium pressure AC discharges in Penning mixtures between insulated electrodes. Discharges in Ne+1%N_2 with glazed electrodes are a suitable experimental model showing the characteristic pulse and continuous discharge modes. The axial optical space time structure of sinus wave sustained model discharges are measured with a scanning device, obtaining characteristic phases of discharge formation. Application of luminous flux method for stationary and dynamic Townsend discharges yields the first Townsend ionization coefficient α, and the comparison of the optical structure of AC discharges with that of DC discharges allows to explain the axial structure and to estimate the space charge effects. (36 refs.)

71813 **Analysis of the kinetic properties and the energy budget of the electrons in the Ar-Hg glow discharge plasma at varying partial pressures and discharge currents.** R.B.Winkler, J.Wilheim, R.Winkler (Zentralinst. fur Elektronenphys., Gasentladungsphys., Rudolf-Seeliger, Greifswald, Germany).
Beitr. Plasma Phys. (Germany), vol.23, no.1, p.25-40 (1983).
By simultaneously solving the Boltzmann equation and the current balance for the electrons the energy distribution function, the electron concentration and resulting macroscopic electron quantities were calculated for the Ar-Hg mixture plasma under conditions typical of fluorescent lamps. Besides the usual external parameters of such diffusion determined discharge plasmas measured values of the electric field strength were employed. The investigations were performed for independent variation of the partial pressures of Ar and Hg as well as of the discharge current in wide ranges of practical interest. The results obtained are discussed and compared with various energy distributions employed up to now and measured values of the electron concentration and temperature as well as with experimental results on the energy budget of this mixture plasma available in the literature. (8 refs.)

71814 **The construction of systems of equations describing gas discharges containing several species of atoms and ions, including stepwise processes, negative ions, and the spatial variation of the temperatures.** H.-B.Valentini (Zentralinst. fur Elektronenphys., Akad. der Wissenschaften, Jena, Germany).
Beitr. Plasma Phys. (Germany), vol.23, no.1, p.51-66 (1983).
The sets of differential equations usually used for the description of the low pressure discharges are underconstrained if several species of atoms and of ions and stepwise processes are taken into consideration. Using the equations of continuity, of momentum transfer, and of energy transfer for each species it is shown that, besides known closing statements for these sets of differential equations, additional conditions are necessary. It is found that the following relatively simple condition is sufficient for positive ions. The radial pressure gradient has to be assumed to vanish at least with the third order as the distance from the axis approaches zero. Various simpler and also more accurate and cumbersome approximations describing non-excited atoms, positive

and negative ions are investigated. Under some conditions one can formulate additional boundary conditions at the wall instead of additional conditions on the axis. (26 refs.)

71815 **Ion-acoustic instabilities of DC discharges in rare gases at low pressures. II. Experimental results in comparison with a one-dimensional kinetic dispersion theory.** R.Leven (Sektion Phys./Elektronik, Ernst-Moritz-Arndt-Univ., Greifswald, Germany), A.Konig.
Beitr. Plasma Phys. (Germany), vol.23, no.1, p.67-76 (1983).
For pt.I see ibid., vol.20, p.129 (1980). The experimental measurements of the propagation properties of self-excited ion acoustic waves in a DC-low pressure column are compared with a one dimensional dispersion theory. The corresponding dispersion relation is developed starting from the linearised Vlasov equation with a Davydov-type collision term. It is shown, that the mean features of the propagation behaviour of the ion acoustic waves can be explained by the theory. The experimental results concerning the dependence of the upper limit frequency of the waves upon the discharge current should be analysed on the base of new results from plasma diagnostics, taking also into account nonlinear and geometrical effects. (10 refs.)

71816 **The state of the theory of vacuum arc cathodes.** E.Hantzche (Zentralinst. fur Elektronenphys., Akad. der Wissenschaften, Berlin, Germany).
Beitr. Plasma Phys. (Germany), vol.23, no.1, p.77-94 (1983).
The physics of vacuum arc cathodes, the advances in their interpretation and the still unsolved problems are summarized. Starting from the experimental experiences the theories of stationary arc spots are described, with their assumptions and variants, their successes and deficiencies. It is shown that an extension of these models by inclusion of non-stationary processes is inevitable. Such processes are suggested and their importance in a theory of the dynamic arc spot is investigated. Finally the role of surface contaminations is discussed, and the general applicability of the vacuum arc models to all kinds of arc electrodes is emphasized. (108 refs.)

71817 **To the energy relations of partial discharges in dielectrics.** A.Veverka.
Elektrotech. Obz. (Czechoslovakia), vol.72, no.4, p.179-81 (April 1983). In Czech.
A relation for the calculation of the power consumed in partial discharges is deduced. Its use makes it possible to determine the power if one were to measure the effective value of voltage on the object, the initial discharge voltage (instantaneous value) on the sine voltage curve of the object and the sum of all charges supplied to the object in one half period of voltage. (2 refs.)

71818 **Discharge behaviour of large electrodes, affected with impurities in air during positive switching voltage.** E.Engelmann (Sektion Elektrotech., Tech. Univ. Dresden, Dresden, Germany).
Elektrie (Germany), vol.37, no.4, p.179-83 (1983). In German.
The ignition conditions and spatial time development of streamer discharges, the streamer discharge-leader discharge transition and the disruption behaviour are described by considering the stochasticity of the discharge processes in sphere-plate-gaps of several metres and the different macro- and micro-geometries of the electrodes. From this data, a technical-physical model of the discharge behaviour of electrodes with impurities is derived. (12 refs.)

71819 **Influence of the temporal voltage curve on the discharge behaviour of large electrode systems, affected with impurities, in air.** S.Laub (Sektion Elektrotech., Tech. Univ. Dresden, Dresden, Germany).
Elektrie (Germany), vol.37, no.4, p.184-9 (1983). In German.
Starting from experimental investigations during switching and lightning voltages, the influence of the effective time and the temporal curve of the electrode voltage on the discharge ignition, the spatial-time discharge development and the disruptive behaviour of large electrode systems, affected with impurities, is further clarified. It appears that the influence of the voltage mode on the discharge processes has to be considered always against the macro- and micro-geometries of the electrodes. Among other things the resulting knowledges shall help to dimension extra-high voltage testing plants in the future with much more safety and to interpret correctly the readings from the plants. (11 refs.)

71820 **Mechanism for the development of the ionization instability in a nonself-sustained gas discharge plasma.** A.S.Kovalev, A.M.Popov, A.T.Rakhimov, N.V.Suetin.
Fiz. Plazmy (USSR), vol.9, no.2, p.392-6 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
The mechanism of the development of an instability formed initially in pre-electrode layers and subsequently propagating to the opposite electrode of a highly conducting channel is investigated. The connection of the proposed mechanism with known volume instabilities is examined. An approximate relationship for the velocity of penetration of the channel to its length and parameters of the discharge is found. (15 refs.) *A.G.C.*

71821 **Theory and calculation of stationary optical breakdown of atomic gases close to the surface of refractory metals.** A.A.Vedenov, G.G.Gladush, A.N.Yavokhin.
Fiz. Plazmy (USSR), vol.9, no.2, p.434-40 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
Low-threshold optical breakdown of atomic gases close to refractory metals is studied analytically and numerically in the framework of a thermal model. It is shown that marked heating of electrons in relation to atoms of the surrounding gas and to the vapour of the metal substantially reduces the breakdown threshold compared with molecular gases. The relationship of the breakdown power density to the temperature of the target, the type of gas and the focusing of the spot is analysed. (11 refs.) *A.G.C.*

71822 **Current density for cold cathode discharge gap in rare gases.** R.Lagushenko, J.Maya (GTE Products Corp., Danvers, MA, USA).
J. Appl. Phys. (USA), vol.54, no.5, p.2255-60 (May 1983).
The authors report experimental current density results for tungsten and yttrium cold cathode discharge gap (j, AC, and DC) as a function of pressure (P_{RG}) for He, Nr, Ar, and (99.9%Ne+0.1% Ar) at 100-220 V. They calculated the discharge gap parameters both for AC and DC cases and compared them to experimental results. Conclusions drawn from this comparison are discussed. (5 refs.)

71823 **Modelling of the low-pressure argon positive column.** C.M.Ferreira (Centro de Electrodinamica, Univ. Tecnica de Lisboa, Lisboa, Portugal), A.Ricard.
J. Appl. Phys. (USA), vol.54, no.5, p.2261-71 (May 1983).
The properties and operating characteristics of the positive column of a low-pressure positive column in argon have been investigated experimentally and theoretically. In the experiments the pressure was varied from 5×10^{-2} to 1 Torr, the discharge current from 0.2-20 mA, and the discharge tube was 2.6 cm inside diameter. Measurements of the axial electric field, electron density and population in ${}^3P_2$ metastable states are reported for various discharge conditions. A test is made of the usefulness of a two-moment theory which is applicable in the intermediate pressure range of this work, i.e. in the transition from inertia-limited to mobility-limited flow of ions to the wall, for the prediction of the operating characteristics. For this purpose, the electron excitation and ionization rates, and transport parameters were calculated from the homogeneous Boltzmann equation. The predicted similarity laws for the positive column are in reasonable agreement with the measurements only in the lower pressure region, i.e. for a pressure-radius product less than about 0.1 Torr cm. The discrepancy between theory and experiment at the higher pressure is, presumably, the result of the authors' failure to correct the calculated ionization rate and effective electron loss rate for the effects caused by ionization from metastables and by space-charge fields. (70 refs.)

71824 **Evidence for a time dependent excitation process in silane radio frequency glow discharges.** G.de Rosny, E.R.Mosburg,Jr., J.R.Abelson, G.Devaud, R.C.Kerns (Solar Energy Res. Inst., Golden, CO, USA).
J. Appl. Phys. (USA), vol.54, no.5, p.2272-5 (May 1983).
A new phenomenon in RF glow discharges has been observed, namely the existence of a strongly time dependent excitation of atomic levels. The observed excitation width of 10 ns (FHWM) is short compared to the 37-ns duration of a half-cycle of the 13.56-MHz applied RF power. This implies a similar time dependence of the density of those electrons responsible for the excitation. Moreover, the excitation propagates through the glow away from the nearer electrode. The nature of this propagation phenomenon is uncertain. These results are deduced from a time resolved study of the $\lambda=288.2$ nm emission from neutral excited silicon, $\mathrm{Si}(4s^1,{}^1P^0)$ and $\lambda=656.3$ nm emission from $\mathrm{H}(n=3)$, generated within the RF silane glow discharge. The radiative lifetimes of these two states are 5.2 and 10 ns, respectively. A study of the Si to H yield ratio, together with some Langmuir probe measurements, indicates that the electrons are thermalized in the glow regions. (11 refs.)

71825 **The ionisation coefficient in Ar-Hg mixtures.** A.L.J.Burgmans, A.H.M.Smeets (Philips Res. Lab., Eindhoven, Netherlands).
J. Phys. D (GB), vol.16, no.5, p.755-62 (14 May 1983).
The ionisation coefficient in Ar-Hg mixtures has been measured for E/n values between 6×10^{-21}V m^2 and 2×10^{-18} V m^2 and for a mercury atom fraction varying from 2×10^{-4} to 2×10^{-2}. The experiments were performed with a parallel-plate apparatus in which the current is measured as a function of the plate separation at constant electric field. The ionisation coefficient was found to be a function of E/n and the mercury atom fraction only. Small admixtures of mercury lead to a large increase in the ionisation coefficient due to Penning ionisation and associative ionisation. From the experimental results the effective rate coefficient for excitation to the appropriate argon states is obtained as a function of E/n, as well as the ratio of the rate coefficients for depopulation of these excited argon states by collisions with argon and mercury atoms respectively. (22 refs.)

71826 **Ionisation and attachment in binary mixtures of SF_6-N_2 and CCl_2F_2-N_2.** M.C.Siddagangappa, C.S.Lakshminarasimha, M.S.Naidu (Dept. of High Voltage Engng., Indian Inst. of Sci., Bangalore, India).
J. Phys. D (GB), vol.16, no.5, p.763-72 (14 May 1983).
Experimental results are presented of ionisation (α) and electron attachment ((η) coefficients evaluated from the steady-state Townsend current growth curves for SF_6N_2 and CCl_2F_2-N_2 mixtures over the range $60\leq E/P\leq240$ (where E is the electric field in V cm^{-1} and P is the pressure in Torr reduced to 20°C). In both the mixtures the attachment coefficients (η_{mix}) evaluated were found to follow the relationship; $\eta_{\mathrm{mix}}=\eta[1-\exp(-\beta F/(100-F))]$ where η is the attachment coefficient of pure electronegative gas, F is the fraction of the electronegative gas in the mixture and β is a constant. The ionisation coefficients (α_{mix}) generally obeyed the relationship $\alpha_{\mathrm{mix}}=\alpha_{N2}(1-F/100)+\alpha_A(F/100)$ where α_{N2} and α_A are the ionisation coefficients of nitrogen and the attaching gas respectively. However, in case of CCl_2F_2-N_2 mixtures, there were maxima in the α_{mix} values for CCl_2F_2 concentrations varying between 10% and 30% at all values of E/P investigated. Effective ionisation coefficients $(\alpha-\eta)/P$ obtained in these binary mixtures show that the critical E/P (corresponding to $(\alpha-\eta)/P=0$) increases with increase in the concentration of the electronegative gas up to 40%. Further increase in the electronegative gas content does not seem to alter the critical E/P. (23 refs.)

71827 **DC nozzle arcs with mild wall ablation.** M.T.C.Fang, D.B.Newland (Dept. of Electrical Engng. & Electronics, Univ. of Liverpool, Liverpool, England).
J. Phys. D (GB), vol.16, no.5, p.793-810 (14 May 1983).
Recent experimental results (Smith et. al., 1980 and Newland et. al., 1982) indicate that nozzle wall ablation can occur even before the arcing current reaches its thermal blocking limit. The wall ablation is caused by intense arc radiation. The evaporated wall material forms an ablation layer which reduces the effective flow area for the arc quenching gas. A theoretical model is established to study the complicated interaction between the ablation layer, the external gas flow and the arc. It has been found that for arcs burning in affinely related nozzles the arc behaviour is controlled by two nondimensional parameters, one of which is similar to the nozzle coefficient (Fang et al, Cowley and Chan). The other nondimensional coefficient, which characterises the effect of wall ablation, is determined by the thermodynamic properties of the nozzle material, the characteristic quantities of the gas and the radiation coefficient for a given upstream electrode material. Three nozzle materials, steel, copper and PTFE, have been studied and two arc quenching gases, SF_6 and air, examined. It has been found that wall ablation greatly reduces the thermal blocking current but only has a marginal effect on the voltage-current characteristics. A comparison with the recent test results (Smith et al, Newland et al) indicates that the theoretical model can adequately describe the nozzle arc behaviour in the presence of wall ablation. (25 refs.)

71828 **Departures from CLTE composition in a nitrogen arc at atmospheric pressure. I. Experimental results.** J.Bacri, M.Lagreca (Centre de Phys. Atomique, Univ. Paul Sabatier, Toulouse, France).
J. Phys. D (GB), vol.16, no.5, p.829-41 (14 May 1983).
The positive column of a wall stabilised arc burning in pure nitrogen at atmospheric pressure is spectroscopically studied. The behavior of local population number densities of atomic and molecular excited levels shows deviations from CLTE composition. These departures are mainly related to diffusion phenomena and radiation escape. (19 refs.)

71829 **Departures from CLTE composition in a nitrogen arc at atmospheric pressure. II. Interpretation of departures from CLTE.** J.Bacri, M.Lagreca (Centre de Phys. Atomique, Univ. Paul Sabatier, Toulouse, France).
J. Phys. D (GB), vol.16, no.5, p.841-54 (14 May 1983).
For pt.I see ibid., vol.16, 829-40 (1983). Departures from chemical equilibrium and from Boltzmann's distribution for excited level populations expected with the assumption of CLTE in a nitrogen plasma at atmospheric pressure are explained by means of a collisional-radiative model taking into account both monatomic and diatomic species, in which transport processes are treated by a parametric approach. (12 refs.)

71830 Lamp model equations taking into account the radial temperature profile of arc plasma. S.Ozaki (Dept. of Electrical Engng., Kobe Tech. Coll., Kobe, Japan), S.Katayama, H.Bo.
J. Illum. Eng. Inst. Jpn. (Japan), vol.67, no.2, p.49-54 (Feb. 1983). In Japanese.
Lamp characteristics are related to the temperature of the arc plasma in high-pressure discharge lamps in which local temperature equilibrium is established. In this paper the relationship between radial temperature profile of the arc plasma measured by optical methods and a mathematical model for lamps is discussed. These discussions can lead to an improvement of the mathematical model after taking into account the temperature profile. The coefficients of the mathematical model equation are determined statistically by using the simplex method. The usefulness of this improved model is discussed, comparing the simulated results with experimental results for discharge lamps operated by resistance ballast. (7 refs.)

71831 Generation and propagation of pressure wave by spark discharge in liquid. H.Tsuchiya, T.Inoue, M.Miyazaki (Kyoto Inst. of Technol., Kyoto, Japan).
Mem. Fac. Ind. Arts Kyoto Tech. Univ. Sci. & Technol. (Japan), vol.31, p.1-13 (Dec. 1982). [received: May 1983]
Deals with energy conversion processes as the basic phenomena in the underliquid electrical discharge forming. Based on the precise observation of electrical and mechanical phenomena, a model is proposed for the process in which the electrical energy released in the electrode gap is converted into the internal energy, the radiation energy of the bubble and energy of the pressure wave in turn. The validity of the model is discussed with regard to both the pressure wave measured by a specially designed device and the electrical energy. It is shown that the pressure level, the size and the possible temperature of the bubble and the form of the pressure wave in liquid can be reasonably evaluated by the model in the case of a shorter electrode gap. In the typical electrode gap, the maximum value of the pressure, that of temperature and that of expansion velocity are 2.8×10^2 MPa, 8.7×10^4K and 160 m/s, respectively. The size of the bubble at the end of the first wave of discharge power is 2.2 mm in radius. The results present the basis for the analytical design of the system of the underliquid electrical discharge forming. (8 refs.)

71832 Ionic space charges generated by evaporating charged liquid sprays. G.S.P.Castle, I.I.Inculet (Univ. of Western Ontario, London, Ontario, Canada), R.Littlewood.
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.59-64
A process is described for collecting fugitive dust emissions which involves the injection of charge into a cloud of particles using a liquid spray. Upon evaporation of the liquid, free ions are produced which quickly adhere to the particles resulting in space charge forces leading to collection on nearby grounded conductors. It is suggested that this process is superior to corona charging for charge injection into a large volume of space. (8 refs.)

71833 Some basic gas and surface discharge phenomena in electrostatics. R.S.Sigmond (Phys. Dept., Norwegian Inst. of Technol., Trondheim, Netherlands), M.Goldman.
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.81-91
In this paper the authors review some recent (and some very old) developments of importance to our understanding of gas and surface phenomena: Unipolar discharges and charge drift in gases. Unipolar charge flow and saturation on insulator surfaces. The initiation of breakdown, and the limitations of Paschen's law, especially in ambient air at μm gap distances: water bridges? Electrochemical effects of Coronas. Streamers and sparks, with some remarks on simulation of long sparks and lightning by sliding discharges on dielectric surfaces. (33 refs.)

71834 Travelling wave coronas as ion source. S.Masuda, H.Nakatani, Y.Shishikui (Dept. of Electrical Engng., Univ. of Tokyo, Tokyo, Japan).
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.93-8
Ion density in weakly ionized plasma in negative and positive streamers produced by travelling wave voltage is estimated by experiments. Then, distortion of the voltage wave due to these streamers are measured and discussed. (5 refs.)

71835 Corona charging of immobilized spherical particles. I.I.Inculet, N.Malik, J.A.Young (Faculty of Engng. Sci., Univ. of Western Ontario, London, Ontario, Canada).
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.99-104
The experiments described in this paper were prompted by some unusual charging results obtained with gravity falling or gun projected particles in the dark space in the vicinity of corona wires. Tests are reported for the charges acquired by metallic spherical particles at both 100 kPa and 50 kPa pressure, immobilized at various distances from a corona wire in cylindrical geometry. The experimental results corroborate the previously reported anomalies, and raise the question whether a significant bi-ionized region exists in the dark region outside the visible glow. (3 refs.)

71836 The effect of electrode characteristics on the measurement of the minimum ignition energy of dust clouds. D.K.Felstead, R.L.Rogers, D.G.Young (Organic Div., Imperial Chem. Industries plc, Manchester, England).
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.105-10
Dust cloud ignition energies, measured using capacitative sparks, were significantly affected by changes in the electrode separation. The minimum energy required for ignition occurred with electrode gaps of between 11 and 13 mm. It was found that the ignition energy increased with electrode material in the order aluminium alloy$<$lead$<$brass$<$stainless steel and decreased as the electrode diameter was reduced from 35 mm to 3.5 mm; below this diameter measurements were affected by corona discharges. 71837 Criterion for the triaxial X-ray residual stress analysis. T.Hanabusa, K.Nishioka, H.Fujiwara (Faculty of Engng., Tokushima Univ., Tokushima, Japan).
Z. Metallkd. (Germany), vol.74, no.5, p.307-13 (May 1983).
In X-ray analysis of periodically distributed short range microscopic residual stresses triaxial stress states have been investigated. The relaxation of the components of residual stresses in spherical inclusions near the surface layer was analysed in order to estimate the weighted-averaged strain. The experimental data measured for silicon particles in a Al-Si alloy as well as the M_6C carbide particles in a highspeed steel were compared with the analytical ones. It was confirmed that the triaxiality has to be considered in X-ray stress measurements if the wave length of the microscopic residual stresses is smaller than the penetration depth of the X-ray used. 71838 The new potential of powder diffraction. Structure determination and refinement using profile analysis technique. H.Manohar (Dept. of Inorganic & Phys. Chem., Indian Inst. of Sci., Bangalore, India).
Curr. Sci. (India), vol.52, no.2, p.39-44 (20 Jan. 1983).
Recent years have witnessed a spectacular revival of interest in powder diffraction. High intensity sources of X-ray and neutrons and improvements in instrumentation have made it possible to collect accurate data in very short times. As a result of advances in computer technology and software development, more data can be processed in a given time; on-line search match can be carried out for the identification of unknown phases. Important advances have also occurred in the indexing of powder patterns and accurate determination of cell parameters. A major development has been the application of the Rietveld profile analysis technique, initially to neutron data and subsequently to X-ray data, as a result of which the number of structure refinements is steadily increasing. The author describes the Rietveld approach and its recent extension to the elucidation of unknown structures in combination and conventional Fourier methods. The significance of this new development in chemistry and materials science is highlighted. (27 refs.)

71839 Neutron scattering equation for chemical short-range order in binary non-crystalline alloy. H.Ruppersberg (Fachbereich Angewandte Phys., Univ. des Saarlandes, Saarbrucken, Germany), C.N.J.Wagner.
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.165-8 (April 1983).
Recently Sakata et al. (1981) proposed a modification of the Bhatia-Thornton equation (1970) for the case of neutron scattering if the elements of the binary alloy under investigation consist of isotopic mixtures. The contributions of the different partial structure factors and of incoherent scattering to the total scattering became clearly changed. The authors show that the original Bhatia-Thornton equation has to be applied without any modifications. (10 refs.)

71840 Fine-structure analysis of spin-polarized low-energy electron diffraction from W(001). R.O.Jones (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany), P.J.Jennings.
Phys. Rev. B (USA), vol.27, no.8, p.4702-11 (15 April 1983).
The theory of spin-polarized low-energy electron diffraction (LEED) is used to analyze the observed fine structure in experimental data for W(001). Within a spin-dependent scattering model, a saturated image barrier provides a satisfactory description, and the analysis leads to a model of the surface potential barrier for W(001). Simpler models, such as those commonly used for LEED intensity calculations, are unable to reproduce all of the observed structure. The complex fine structure of the spin-polarized LEED intensity curves as interpreted in terms of the interaction between Bragg peaks, spin-dependent features, and barrier scattering effects. Resonance effects do not need to be involved. (31 refs.)

71841 Dynamical effects of the surface potential barrier in very low energy electron diffraction. J.Lopez (Univ. of Claude Bernard, Villeurbanne, France), J.C.Le Bosse, C.Gaubert, R.Baudoing, Y.Gauthier.
Surf. Sci. (Netherlands), vol.126, no.1-3, p.286-93 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
On the basis of algebraical results examplified with exact computations, the authors investigate the dynamical effects associated with the presence of the surface potential barrier in very low energy electron diffraction (VLEED). These effects essentially have three origins: (i) the diverging phase of the reflection amplitude from metal back to metal leads to rapid oscillations of intensity located below emergence thresholds, the maxima of which are arranged in a Rydberg-like series. This effect, wrongly attributed to a resonance process, is actually due to a simple interference mechanism (ii) The singularity near zero of the transmission amplitude of the barrier from metal to vacuum leads to a discontinuity in the current of non-specular beams at their emergence threshold. (iii) The interference between the waves directly reflected at the surface barrier and at the atomic planes generally induces large modifications of the intensity profiles spreading out on the whole VLEED energy range. Thus the approximation consisting in neglecting the reflection at the surface barrier is inadequate. (14 refs.)

61.16D Electron microscopy determinations

71842 The specimen thickness effect upon the electron microscope image contrast transfer of amorphous objects. P.Bonhomme, A.Beorchia (Lab. de Microscopie Electronique, Reims, France).
J. Phys. D (GB), vol.16, no.5, p.705-13 (14 May 1983).
From experimental measurement the authors show that amorphous carbon specimens imaged by 100 keV conventional transmission electron microscopy (CTEM), with thicknesses as large as 100 nm behave like weak phase objects. The defocus of the phase transfer contrast function cannot be evaluated from the exit surface plane of the object but may be from its middle plane. A theoretical model explaining these results is propounded. (13 refs.)

71843 Problems of interpretation in high resolution electron microscopy. A.Howie (Cavendish Lab., Cambridge Univ., Cambridge, England).
J. Microsc. (GB), vol.129, pt.3, p.239-51 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
Current assumptions in wave aberration theory and specimen scattering theory are reviewed. More quantitative image simulations would be valuable as well as use of a wider range of imaging techniques, particularly STEM. The severe difficulties of high resolution three-dimensional reconstruction are described and illustrated. (39 refs.)

71844 The STEM approach to the imaging of surfaces and small particles. J.M.Cowley (Dept. of Phys., Arizona State Univ., Tempe, AZ, USA).
J. Microsc. (GB), vol.129, pt.3, p.253-61 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
The characteristics of scanning transmission electron microscopy, which makes it amenable to recording and image processing procedures, the possibility of correlating the image data with microdiffraction patterns and microanalysis of chosen small regions and the possibilities for combining several different image signals obtained simultaneously. Images obtained from surfaces using reflected diffraction beams may be very sensitive to variations of surface structure but the resolution, depth of focus and contrast of the images are strongly dependent on the nature of the surface and the aperture sizes used in the microscope. Microdiffraction patterns may be obtained from small surface features. Electron energy loss analyses of the diffracted beams provides sensitive indications on surface electron excitations. Microdiffraction patterns obtained in transmission from regions of 1-5 nm diameter provide valuable information on the structure and defects of small crystals, such as those of platinum and gold which are of interest in relation to the study of catalysts. (17 refs.)

71845 The use of moire techniques to measure rigid body displacements. R.C.Ecob, W.M.Stobbs (Dept. of Metall. & Materials Sci., Cambridge Univ., Cambridge, England).
J. Microsc. (GB), vol.129, pt.3, p.275-84 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
The relative advantages and disadvantages of a variety of experimental electron microscopical techniques for the measurement of rigid body displacements are considered. The principles of the application of a moire method of great simplicity and high potential accuracy are then further discussed as are the experimental difficulties associated with the superposition of suitable reference lattices on a substrate. The method is then applied to obtain an upper limit for the rigid body displacement at {111} $\Sigma 3$ twin boundaries in stainless steel. (13 refs.)

71846 Coherency strain fields: magnitude and symmetry. A.J.Porter, R.C.Ecob, R.A.Ricks (Dept. of Metall. & Materials Sci., Cambridge Univ., Cambridge, England).
J. Microsc. (GB), vol.129, pt.3, p.327-36 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
Considers the various methods available for the measurement of small values of in-situ lattice misfit between a coherent particle and the matrix. Examination of such misfits by Asby-Brown contrast imaging, moire fringe measurements, lattice fringe imaging and convergent beam electron diffraction (CBED) is considered, and the results obtained by these techniques are compared. In addition, the nature of the strain fields in the matrix adjacent to a coherent misfitting particle is examined using CBED. (15 refs.)

71847 Techniques for investigating structure and composition with high spatial resolution. J.B.Vander Sande (Dept. of Materials Sci. & Engng., MIT, Cambridge, MA, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.153-60
The techniques of scanning transmission electron microscopy and atom probe field ion microscopy are briefly described. The advantages of these techniques for high spatial resolution compositional analysis are discussed and examples cited. (4 refs.)

61.20 CLASSICAL, SEMICLASSICAL, AND QUANTUM THEORIES OF LIQUID STRUCTURE

(for kinetic and transport theory, see 51.10; for electronic states, see 71.; for liquid helium, see 67.)

71848 Molecular properties in liquid phase. L.M.Sese (Univ. Nacional de Educacion a Distancia, Madrid, Spain), M.Fernandez.
THEOCHEM (Netherlands), vol.10, p.261-4 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).
A model for studying environmental effects on the molecular properties is proposed. Basic concepts of statistical mechanics and quantum chemistry are linked in a natural way in the theory. Liquids are considered composed by molecules whose electronic wavefunctions are not the same as those in the isolated molecules. The electronic wavefunction for the diluted molecule can be obtained from any molecular orbital formalism, introducing appropriate corrections in the monoelectronic hamiltonian to account for molecular interactions. To determine the magnitude of these corrections, statistical mechanics atom-atom distribution functions of the considered liquid are used. The perturbation method is used to obtain molecular orbitals of the molecule in the liquid, from molecular orbitals of the isolated molecule. In order to study the practical features of the proposed model, the authors have applied it to carbon disulphide in the liquid phase for three different densities. The radial distribution functions at 282.16K has been obtained by using the Monte-Carlo method. The molecular orbitals have been calculated by means of the CNDO/2 method. (3 refs.)

71849 Binary theory of dephasing in liquid solutions. I. The non-Markovian theory of encounters. A.A.Kipriyanov, A.B.Doktorov, A.I.Burshtein (Inst. of Chem. Kinetics & Combustion, Novosibirsk, USSR).
Chem. Phys. (Netherlands), vol.76, no.2, p.149-62 (15 April 1983).
A non-Markovian version of encounter theory is proposed which consistently takes into account fast dissipative processes. Kinetic equations of vibrational molecular states dephasing at binary encounters in solutions are derived in terms of this theory. A particular case of fast molecular rotation is considered. The characteristic impurity dephasing time is calculated for the case of weak molecular interactions. (44 refs.)

71850 Binary theory of dephasing in liquid solutions. II. Motion-transformed isotropic Raman spectra. A.A.Kipriyanov, A.B.Doktorov, A.I.Burshtein (Inst. of Chem. Kinetics & Combustion, Novosibirsk, USSR).
Chem. Phys. (Netherlands), vol.76, no.2, p.163-74 (15 April 1983).
For pt.I see ibid., vol.76, no.2, p.149 (1983). The non-Markovian theory of encounters is applied to calculations of impurity dephasing kinetics, corresponding Raman spectra and their moments. The theory is checked against the model of suddenly switched interactions and then applied to linewidth calculations under dynamic and stochastic dephasing. The former occurs for isotropic short-or long-range interactions. The latter takes place in the case of anisotropic dipole-dipole interactions modulated by fast rotation. Within perturbation theory the line is stated to be motion-narrowed in the former case and independent of translational motion in the latter case. If the interaction is strong, the line is motion-broadened in both cases but in different ways depending on whether the interaction was switched on by a jump or by continual diffusion. Perturbation theory becomes inapplicable to impurity dephasing much earlier than is conventionally assumed. (39 refs.)

71851 The shape of the Lorentz cavity and the internal field in anisotropic fluids. D.A.Dunmur (Dept. of Chem., Univ. of Sheffield, Sheffield, England), R.W.Munn.
Chem. Phys. (Netherlands), vol.76, no.2, p.249-53 (15 April 1983).
The predictions of the ellipsoidal Lorentz cavity model for different cavity axial ratios are compared with the predictions of a microscopic molecular

crystal model for different molecular axial ratios. The models agree when the cavity depolarisation factor equals the crystal Lorentz factor. Numerical calculations show that the axial ratio of the cavity equivalent to the molecule is roughly equal to the molecular axial ratio up to ≈ 5, but increases rapidly thereafter. For molecular axial ratios of 9 and above there is no equivalent cavity. Implications of the results for the internal field in liquid crystals are considered. (28 refs.)

71852 Law of corresponding states of uni-univalent molten salts. M.Harada, M.Tanigaki (Inst. of Atomic Energy, Kyoto Univ., Kyoto, Japan), Y.Tada.
Ind. & Eng. Chem., Fundam. (USA), vol.22, no.1, p.116-21 (Feb. 1983).
A method to yield a law of corresponding states for alkali halides was developed. The complicated pair potential between the constituting ions was simplified to Coulomb and soft-core potentials. The state functions of real molten salts were mapped to the domain of the reference salt, whose ions interact through the hard-sphere core potential and the Coulomb potential by scaling the soft-core potential. The validity of the mapping was demonstrated for potassium chloride by use of the computer simulation of L.V. Woodcock et al. (1971). The corresponding-states correlation for the thermodynamic properties of alkali halides was obtained in the mapped space. A simplified corresponding-states correlation using the characteristic temperature and the molar volume was also discussed. (18 refs.)

71853 A van der Waals model of chiral mixtures using a chiral Lennard-Jones potential. Applications to the Pasteur experiment and phenomena in chiral solvents. P.E.Schipper, P.R.Harrowell (Dept. of Theoretical Chem., Univ. of Sydney, Sydney, NSW, Australia).
J. Am. Chem. Soc. (USA), vol.105, no.4, p.723-30 (23 Feb. 1983).
Much of the understanding of the behavior of simple fluids stems from the combination of a simple Lennard-Jones potential and a subsequent van der Waals approach to the statistical thermodynamics of such fluids. In this paper, both are generalized to incorporate the effects of chirality as a basis for the discussion of the properties of chiral mixtures at the simplest level. In this way, the role of chirality in leading to characteristic thermodynamic effects may be rigorously defined. Although the model may be too simple to apply quantitatively in that chiral mixtures are frequently relatively complex in structure, it serves as a natural starting point for understanding and defining the role of chirality in thermodynamic phenomena in the solution phase. The model is applied to a number of solution phenomena, such as the possible role of solution configurations in spontaneous resolutions (the Pasteur experiment), and equilibrium shifts of labile racemates or differential enantiomeric solubilities in chiral solvents. (30 refs.)

71854 Computer simulation of liquid anisotropy. IV. Terms to second order in the external field of force. M.W.Evans (Chem. Dept., Univ. Coll. of Wales, Aberystwyth, Wales).
J. Chem. Phys. (USA), vol.78, no.9, p.5403-7 (1 May 1983).
The method of molecular dynamics computer simulation is extended to deal with liquid anisotropy induced by the interaction of an external electric (or magnetic) field with anisotropy of polarizability. The resulting Langevin functions follow accurately the analytical results of Kielich (1970). The new method is applied to extract the details of rotation/translation interaction in a moving frame of reference. The appropriate first order correlation functions are much more oscillatory in the presence of a strong external field. (29 refs.)

71855 Evaluation of the SSC/LHNC, SSCF and PY approximations for short ranged, anisotropic potentials. P.T.Cummings (Depts. of Mech. Engng. & Chem., State Univ. of New York, Stony Brook, NY, USA), J.Ram, R.Barker, C.G.Gray, M.S.Wertheim.
Mol. Phys. (GB), vol.48, no.6, p.1177-207 (20 April 1983).
Three approximations for the orientational correlation function of molecular fluids (the single superchain/linearized hypernetted chain (SSC/LHNC), single superchain f-expansion (SSCF) and Percus-Yevick (PY) approximation) are evaluated in the dense liquid state for a fluid interacting with short ranged anisotropic interactions. These interactions are prototypical of the forces that determine the nonspherical shape of symmetric linear molecules. The authors find that SSC/LHNC is very poor, failing to predict many of the structural features present in the Monte Carlo (MC) simulation results. The PY and SSCF approximations produce much better results; however, neither approximation is completely satisfactory. (27 refs.)

71856 Nonpolar solute-water pair correlation functions—a comparison between computer simulation and theoretical results. A.Tani (Istituto di Chimica Fisica, Univ. di Pisa, Pisa, Italy).
Mol. Phys. (GB), vol.48, no.6, p.1229-40 (20 April 1983).
The microscopic theory of the solvation of nonpolar solutes in water proposed by Pratt and Chandler (1977) has been generalized in order to obtain separate solute-oxygen and solute-hydrogen radial distribution functions, $g(r)$. The $g(r)$s predicted by this method for a spherical solute have been tested by comparison with the corresponding functions from two computer simulation studies. The water-water interactions were described by the configuration interreaction potential (CI) in both cases. The agreement between theoretical and simulation results is good for the solute-oxygen $g(r)$, less so for the solute-hydrogen function. Moreover, the influence of the model of water on the calculated solute-solvent $g(r)$s has been examined by comparing results obtained with partial structure functions derived from the CI model and from recent neutron diffraction measurements. It is found that CI model and real water yield remarkably different solute-water radial distribution functions. Finally, the solvation of a model two-site solute has been studied for various bond lengths and the results confirm that when the space between the sites is sufficient to host a water molecule, the solvation of each site is the same as that of an isolated site, with respect to oxygen as well as hydrogen. (26 refs.)

71857 Equilibrium properties of a 2-2 electrolyte model—Monte Carlo and integral equation results for the restricted primitive model. S.A.Rogde (Dept. of Chem., Univ. of Bergen, Bergen, Norway), B.Hafskjold.
Mol. Phys. (GB), vol.48, no.6, p.1241-53 (20 April 1983).
Thermodynamic and structural results are reported for the restricted primitive model (RPM) in the 2-2 aqueous electrolyte regime. The regime corresponds to salt concentrations from 0.0001 M to 3 M, at 25°C. The Monte Carlo method, the HNC approximation and a PY-like integral equation were used in order to examine the model system. Good agreement is found between the various methods, except at the intermediate concentrations, where the HNC overestimates the amount of triple-ion aggregates ($+-+$ and $-+-$). (27 refs.)

71858 Dielectric friction on a polar molecule rotating in a fluid. B.U.Felderhof (Inst. fur Theoretische Phys., RWTH Aachen, Aachen, Germany).
Mol. Phys. (GB), vol.48, no.6, p.1269-81 (20 April 1983).
The author considers the continuum model for dielectric friction on a polar molecule rotating in a fluid. Taking account of electrohydrodynamic coupling he calculates the frequency dependent rotatory friction coefficient to second order in the strength of the permanent dipole moment. (14 refs.)

71859 Dielectric friction on an ion rotating in a fluid. B.U.Felderhof (Inst. fur Theoretische Phys., RWTH Aachen, Aachen, Germany).
Mol. Phys. (GB), vol.48, no.6, p.1283-8 (20 April 1983).
The author considers the continuum model for dielectric friction on an ion rotating in a polar fluid. Taking account of electrohydrodynamic coupling he evaluates the frequency dependent rotatory friction coefficient for arbitrary values of the charge. (12 refs.)

71860 Thermodynamical behaviour and radial distribution functions of dilute systems of charged rigid spheres. S.Ciccariello (Istituto di Fisica 'G. Galilei', Padova, Italy), D.Gazzillo.
Mol. Phys. (GB), vol.48, no.6, p.1369-81 (20 April 1983).
The excess thermodynamical functions and the radial distribution functions for dilute systems of charged rigid spheres with different radii and/or electrical valences have been evaluated by two different methods. One consists in taking into account the first order perturbative correction in the Meeron renormalized cluster expansion. The other one leans upon a simple variational optimization procedure. The results are compared with available hypernetted chain and Monte Carlo results. (15 refs.)

71861 Microscopic mechanism of the cage effect in simple liquids. Y.Endo (Dept. of Phys., Tokyo Metropolitan Univ., Tokyo, Japan), H.Endo.
Phys. Lett. A (Netherlands), vol.95A, no.2, p.92-4 (18 April 1983).
Atomic motions in a soft-core liquid are classified by molecular dynamics simulation into subgroups which are characterized by the number of atoms surrounding a central atom. It is found that the rigidity and lifetime of the microstructure of the cage depend on the local environment around the central atom. (7 refs.)

71862 Computer simulation of the phases of two-dimensional Lennard-Jonesium: evidence for first-order transitions. F.F.Abraham (IBM Res. Lab., San Jose, CA, USA).
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.75-95
An extensive computer simulation investigation of the structure, thermodynamics and phase stability of the two-dimensional Lennard-Jones system is presented, with special emphasis on the low-pressure melting regime of the phase diagram. This investigation includes isobaric-isothermal Monte Carlo and molecular dynamics simulations of the various phases of the two-dimensional Lennard-Jones system and of the melting and vaporization processes, isodensity-isothermal Monte Carlo simulations of two-phase coexistence between crystal and liquid, the determination of the phase diagram, the establishment of the thermodynamic melting temperature, and the determination of the physical significance of the Kosterlitz-Thouless-Feynman dislocation model for melting in relation to the stability of the crystalline phase. The author concludes that the phase diagram of the Lennard-Jones system in two dimensions is qualitatively similar to that in three dimensions. (58 refs.)

The pressure tensor at the planar surface of a liquid ....See Entry 72183

61.25 STUDIES OF SPECIFIC LIQUID STRUCTURES

(see also 61.40 Amorphous and polymeric materials)

71863 Cooperative behaviour in liquids. G.J.Evans (Edward Davies Chem. Labs., Univ. Coll. of Wales, Aberystwyth, Wales).
J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.4, p.547-58 (April 1983).
Evidence is presented for the existence of strong cooperative behaviour in the liquid state. It is suggested that the far-infrared spectrum of CH_3CN is composite in nature and that only a small portion may be attributed to the so-called 'Poley absorption' supposedly characteristic of polar liquids in the far-infrared. This is in accord with a recent conclusion of other authors in a quite independent investigation. There is strong evidence from a number of spectroscopic methods that a strong local order exists in acetonitrile that persists in solutions down to 10% and less. The consequence of this association is that absorptions other than those arising from single-particle motions (which peak at ca. 60 cm^{-1}) contribute to the total profile which has a maximum absorption of ca. 100 cm^{-1}. Detail is resolved on the low-frequency side of the far-infrared spectral profile that has not been reported previously. In particular, a strong feature at the frequency of maximum absorption, clearly resolved with an interferometric system, appears to be confirmed with a line from a tunable laser system. At this stage it is only possible to speculate on the origin of this detail but there is significant evidence available that suggests a contribution to the profile from the motions of aggregates of molecules. A whole set of intermolecular vibrational transitions is then possible and they may strongly overlap each other. The author presents other new observations that also seem to reflect strong cooperative behaviour in the liquid state. (23 refs.)

71864 Multidetector scattering as a probe of local structure in disordered phases. N.A.Clark (Dept. of Phys., Univ. of Colorado, Boulder, Co, USA), B.J.Ackerson, A.J.Hurd.
Phys. Rev. Lett. (USA), vol.50, no.19, p.1459-62 (9 May 1983).
The local translational structure of a two-dimensional colloidal liquid is observed by use of cross correlation of the intensity fluctuations of light scattered by the liquid through two different wave vectors. The utility of multidetector scattering in probing multipoint correlations in disordered phases is thereby demonstrated unambiguously. (9 refs.)

71865 Relation between the chemical short-range order in liquid and amorphous alloys. C.N.J.Wagner, H.Ruppersberg (Dept. of Materials Sci. & Engng., Univ. of California, Los Angeles, CA, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.91-102
Recent advances in both diffraction theory and experiment have led to the determination of the topological and chemical short-range order in liquid alloys and metallic glasses. In binary alloys, three partial interference functions (or partial structure factors) must be determined to evaluate the Warren chemical short-range order parameter α. Examples of recent attempts to determine α in binary liquid and glass alloys are given. In most glasses studied so far evidence exists for the occurrence of unlike nearest neighbor ordering which must be present in the liquid state. (27 refs.)

(see also 64.70M Transitions in liquid crystals)

71866 Mesomorphic properties of some nitro substituted azomethines. V.Reiffenrath, F.Schneider, N.K.Sharma (Physikalische Chem., Univ. Siegen, Siegen, Germany).
Indian J. Chem. A, vol.21A, no.9, p.869-72 (Sept. 1982). [received: May 1983]
The homologous series of 4′-*n*-alkoxybenzylidene-4-nitroanilines (I) and 4″-*n*-alkoxybenzylidene-4′-amino-4-nitrobiphenyls (II) have been synthesized and their mesomorphic properties investigated. Generally, the alkoxybenzylidene-nitroanilines show only monotropic nematic and smectic phases, whereas the biphenyl derivatives exhibit broad nematic and smectic phases. The smectic phases of the biphenyl compounds are of the S_B and S_E types which are scarcely observed for liquid crystals with polar terminal groups. X-ray studies show that the smectic phases of both the series exhibit bilayer structures. (13 refs.)

71867 Rigid backbone polymers: thermal behavior of polyhexylisocyanate mesomorphic solutions. P.Navard, J.M.Haudin (Ecole Nat. Superieure des Mines de Paris, Paris, France), S.M.Aharoni.
J. Polym. Sci. Polym. Lett. Ed. (USA), vol.21, no.4, p.271-5 (April 1983).
Many polyisocyanates are able to form lyotropic solutions when mixed with numerous solvents. One of the most important results in the comparison between experimental data and the theory developed by Flory et al. (1978). All the main features of this theory were verified, i.e. the occurrence of a biphasic interval, the qualitative agreement of the phase diagrams, and the partitioning between isotropic and anisotropic phases. The thermal behavior of polyhexylisocyanate (PHIC)-toluene solutions is investigated. (23 refs.)

71868 Diffusion and orientability of rigid-rod molecules. J.A.Odell, E.D.T.Atkins, A.Keller (H.H. Wills Phys. Lab., Univ. of Bristol, Bristol, England).
J. Polym. Sci. Polym. Lett. Ed. (USA), vol.21, no.4, p.289-300 (April 1983).
Thermally stable aromatic polymers possessing a high degree of chain linearity and stiffness form liquid-crystal-like solutions in strong acid solvents. The polymers are processed from the nematic state in fibers and films of exceptional stiffness and strength. A knowledge of the response of such systems to orientational flow fields and of subsequent relaxation processes is central to the processing of such polymers and is of considerable theoretical interest. An important recent theory by Doi (1975) and Doi and Edwards (1978) provides the basis of understanding the behavior of strongly interacting systems of rigid rods, at least at moderate concentration. Methods have been developed to enable the study of the response of flexible and semiflexible polymer chains to well-defined extensional flow fields. One such method is the four-roll mill providing a pure-shear extensional flow field over a rigid molecule to such flow fields. The results provide a method for the assessment of orientability, expressed in terms of rotational diffusion coefficient, as a function of strain rate (orientation) and concentration for solutions which are isotropic at rest. The existing theories account qualitatively for many of the observed effects, but quantitative agreement is poor. The theoretical basis is critically reexamined, and modifications are presented which can bring experimental results and theory quite closely to agreement. Even so, it seems that in wider generality a new and different basic approach needs to be taken. (15 refs.)

71869 The circular dichroism of cholesteric cellulose acetate solutions; dependence on molecular weight. P.Sixou, J.Lematre, A.T.Bosch, J.M.Gilli, S.Dayan (Lab. de Phys. de la Matiere Condensee, Univ. de Nice, Nice, France).
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.277-83 (1983).
Concentrated solutions of cellulose acetate in trifluoroacetic acid are cholesteric liquid crystals. The circular dichroism of solutions of two samples of cellulose acetate of different molecular weights has been examined. Under the same conditions of temperature and polymer concentration by weights the solutions of the higher molecular weight polymer gave circular dichroism peaks at higher wavelength and of higher intensity and are therefore presumably more highly ordered. Solutions containing mixtures of polymer chains of two different lengths gave a single circular dichroism peak which occurred at a wavelength intermediate between those corresponding to the two polymer species. The intensity of the peak was, however, considerably reduced, in some instances being lower than that which would have been given by either component taken on its own. (19 refs.)

71870 Pretransitional behavior of 8-12 CB. Zhang Shu-Lin, Peng Zheng-Yu, Wu Jin, Shen Tie-Han, Wu Nai-Qiang (Dept. of Phys., Peking Univ., Beijing, China).
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.295-307 (1983).
The magnetic birefringence in the isotropic phase vs. temperature for the liquid crystal alkyl cyanobiphenyls (C_nH_{2n+1}-biphenyl-CN), n=8-12, has been measured. The inverse of the Cotton-Mouton coefficient values, R, vs. temperature T were plotted. The shape and the influence of the smectic phase on the 'bending down' in the R vs. T curve near the clearing point T_c are discussed. The so-called 'odd-even effect' is observed. In the experiments on 9 CB and 11 CB, the 'inflection' or 'saturation' in the 'bending down' region mentioned in the work of Coles and Strazielle, and Pouligny et al., respectively, are not observed. (18 refs.)

71871 The influence of an external electric field on the structure of chiral Sm C* liquid crystal. M.Glogarova, L.Lejcek, J.Pavel, V.Janovec, J.Fousek (Inst. of Phys., Czechoslovak Acad. of Sci., Prague, Czechoslovakia).
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.309-25 (1983).
The mechanism of a field induced transition from the helical Sm C* to Sm C structure in a DOBAMBC liquid crystal situated between two glass plates has been studied by optical methods. The important role of a regular system of twist disclination lines (dechiralization lines) in unwinding the helical structure by an electric field has been revealed. A simplified model of $\pm 2\pi$ twist disclination pairs is proposed which describes the unwinding of the Sm C* structure. Under the external electric field the pairs of $\pm 2\pi$ twist disclinations move and annihilate each other and thus effectively unwind the helical structure of the sample. Critical fields for switching the helical Sm C* structure, as well as the unwound structure, are estimated. (28 refs.)

71872 Order parameters for isomeric phenyl substituted anthraquinone dyes dissolved in nematic liquid crystals mixtures—influence of the host. J.Cognard, T.Hieu Phan, N.Basturk (ASULAB SA, Neuchatel, Switzerland).
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.327-40 (1983).
Substitution of the anthraquinone ring system has provided dyes suitable for guest-host applications. In general, one seeks to elongate the anthraquinonic system through a fourth ring. Different molecular structures have been proposed which all have similar ordering in the liquid crystalline host. Surprisingly, the 2-*p*-alkoxyphenyl substituted 1,5-dihydroxy-4,8-diaminoanthraquinones have a higher order parameter in liquid crystalline mixtures of positive dielectric anisotropy made from cyano substituted molecules. They lose this property in a system consisting of molecules without cyano groups at the termini of the molecular axes. The properties of two isomeric substituted anthraquinone dyes in different hosts are compared in order to illustrate the considerable influence that dye-liquid crystal interactions may have on the dye order parameter. (10 refs.)

71873 Cyano mesogens: a new interpretation of the structure of the bilayer smectic A phase. D.Guillon, A.Skoulios (Centre de Recherches sur les Macromolecules, Strasbourg, France).
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.341-52 (1983).
A new model describing the bilayer structure of the smectic A mesophases observed with cyano mesogens is proposed. The authors' interpretation is based upon recent experimental X-ray studies of binary mixtures containing a cyano mesogen on one hand and a non-polar one on the other, with either one or two aliphatic chains in the molecules. In this model, the smectic layers are formed of the intimate mixture of single molecules and of dimers described as being pairs of molecules associated head-to-head. As a result, the degree of dimerization is far from unity due to the steric hindrance of the aliphatic chains; it decreases notably when the average number of aliphatic chains in the system increases. (12 refs.)

71874 Light scattering from nematic liquid crystals in a nonuniform velocity field. E.A.Jacobsen, J.B.Swift (Dept. of Phys., Univ. of Texas, Austin, TX, USA).
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.353-7 (1983).
Fluctuations about a nonequilibrium steady state of a nematic liquid crystal subject to small, linear shear, are studied by means of a generalized Langevin method. The authors find a symmetric broadening of the director power spectrum and estimate the numerical size of the effect of a typical material. (8 refs.)

71875 Reexamination of the theory and experimental results of optically induced molecular reorientation and nonlinear diffractions in nematic liquid crystals: spatial frequency and temperature dependence. I.C.Khoo (Dept. of Phys. & Astron., Wayne State Univ., Detroit, MI, USA).
Phys. Rev. A (USA), vol.27, no.5, p.2747-50 (May 1983).
Presents a detailed calculation of, and experimental results on, the dependence of degenerate four-wave mixing and nonlinear diffraction in a nematic film on the spatial frequency of the intensity grating generated by two overlapping lasers. The explicit analytical expressions allow a critical reexamination of previous results and lead to better agreement between theory and experiments. Some of the previous theoretical and experimental results are reconfirmed. The author also presents further detailed results on the temperature dependence of nonlinear diffraction. (9 refs.)

71876 Absorption edge of liquid crystal TBBA and the effect of an electric field on the spectra. T.P.Myasnikova, G.N.Zhizhin, N.I.Afanas'eva (Inst. of Spectroscopy, Acad. of Sci., USSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1770-2 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3128-30 (Oct. 1982). [received: April 1983]
Terephthal-bis-butylaniline (TBBA), which has five liquid-crystal phases, is among the most studied of liquid crystals. The authors report a study undertaken to investigate the changes in the edge region of the absorption spectra during the phase transitions, to elucidate the role of exciton-phonon interactions, and to determine the effect of an alternating electric field on the position of the edge. (7 refs.)

71877 Dependences of the parameters of the liquid-crystal order on the molecular hyperpolarizability. G.A.Lyakhov, Yu.P.Svirko, I.M.Fedotova (P.N. Lebedev Phys. Inst., Acad. of Sci., Moscow, USSR).
Sov. J. Quantum Electron. (USA), vol.12, no.11, p.1525-6 (Nov. 1982). Translation of: *Kvantovaya Elektron., Moskva (USSR)*, vol.9, no.11, p.2341-3 (Nov. 1982). [received: May 1983]
An anharmonic oscillator model of an anisotropic molecule is used to calculate the changes in the temperature of a nematic phase transition and in the pitch of a cholesteric helix as a function of the cubic hyperpolarizability. The results obtained are used to explain the nonmesogenic nature of anisotropic molecules with an internal (intramolecular) charge transfer. (7 refs.)

71878 An analysis of small-angle X-ray scattering by smectic polymers. Yu.S.Lipatov, V.V.Tsukruk, V.V.Shilov.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.543-9 (April 1983). In Russian.
Small-angle X-ray scattering has been used to study some polymers with side mesogenic groups. One-dimensional correlation functions are obtained by the Fourier transformations of intensity data. The electron density distribution in the layers can be represented as a two-step function with a higher hard nuclei packing density of the mesogenic groups. A model is suggested to represent the polymer microstructure as 20-55 nm 'layer packets' inside which there exists a positional correlation of the layer arrangement. (23 refs.)

61.40 AMORPHOUS AND POLYMERIC MATERIALS

(see also 64.70P Glass transitions 81.20P to 81.20T, and 81.60 Materials science)

71879 Crystallization of Fe-P amorphous alloys as studied by the EDXD method. E.Hiltunen (Dept. of Phys. Sci., Univ. of Turku, Turku, Finland), L.Takacs.
J. Mater. Sci. (GB), vol.18, no.5, p.1515-21 (May 1983).
The crystallization of amorphous Fe-P alloys, made by electrodeposition were studied using energy dispersive X-ray diffraction (EDXD), thermomagnetic, and Mossbauer measurements. EDXD proved to be especially useful, because its very short exposure time enabled the authors to perform isothermal crystallization measurements with practically continuous control by means of diffraction spectra. By measuring the intensity of the appropriate diffraction lines, the crystallization kinetics of each phase could be recorded simultaneously. At 610K the crystallization of an $Fe_{81.2}P_{18.8}$ amorphous alloy was found to start within 5 minutes with the primary crystallization of α-iron. This step is followed by the eutectic crystallization of the stable phases α-iron and Fe_3P. (9 refs.)

71880 Study by X-ray and neutron diffraction of the structure of ex-carbonyl amorphous iron. J.-P.Lauriat (Lab. de Cristallographie et Phys. des Materiaux, Univ. de Paris-Sud, Orsay, France).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.77-91 (April 1983).
Ex-carbonyl amorphous iron is a heterogeneous finely powdered material. Its texture established by standard physico-chemical analysis is compatible with the diffraction data: two phases have been identified, an amorphous ferromagnetic phase homogeneous up to 300 Å containing less than 1% carbon in solution and an unstable phase coming from a part of the CO from the decomposition of carbonyl and representing 7.2% by weight. The pair distances from both X-ray and neutron diffraction spectra are identical after taking into account measurement error: the shorter pair distances are those already found in icosahedral structures, and higher distances, identified up to 19 $Å^{-1}$, are simple exact combinations of the shorter ones. (16 refs.)

71881 Computer modelling of amorphous magnetic materials. M.E.Lines (Bell Labs., Murray Hill, NJ, USA).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.1-25 (April 1983).
A review of the techniques of computer modelling of amorphous magnetic materials is presented. The magnetic materials discussed fall mainly into three categories, the ferromagnetic transition-metal metalloid alloys, the 'ferrimagnetic' transition-metal rare-earth alloys, and the speromagnetic amorphous magnetic insulators. Although all have primarily been computer modelled using simulations based on a common structural concept—that of the dense random packing of hard spheres (DRPHS)—details of the various modelling techniques are different for each. After introducing the basic DRPHS technique for the simplest possible case involving spheres of one size, and a discussion of its relevance in describing the rather unstable amorphous elemental magnetic metals, the importance of a subsequent relaxation (or energy minimization) of the hard-sphere aggregation into 'soft'-sphere equivalents is expressed. Comparison with experiment occurs primarily via the diffraction measurement of radial distribution functions. The review then progresses to an analysis of binary hard-sphere asemblies corresponding to stable amorphous magnetic alloys, and sets out convincing experimental evidence for the importance of chemical bonding in the metalloid systems. It focuses, in particular, on the ways in which such bonding forces can be accommodated within computerized building schemes both at the hard-sphere and soft-sphere levels of the development. Although chemical constraints are certainly less severe in the amorphous transition-metal rare-earth alloys, evidence for their possible importance in this context is also covered. (107 refs.)

71882 First investigations of the vitreous crystal phase of 1-cyanoadamantane obtained by quenching of the plastic phase. J.L.Sauvajol, M.Foulon, J.P.Amoureux, J.Lefebvre, M.Descamps (Lab. de Dynamique des Cristaux Moleculaires, Univ. de Lille I, Villeneuve d'Ascq, France).
J. Phys. Colloq. (France), vol.43, no.C-9, p.521-4 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
It has recently been shown the possible existence of glasses of a new kind, obtained by the quenching of some molecular crystals initially in their disordered rotator phase (plastic-crystals). In this phase the average translational order of the plastic phase is preserved but the orientational disorder would be frozen. The authors report here the results of preliminary experiments on the 1-cyanoadamantane whose plastic phase can be easily supercooled even when operating with single crystals. These experiments are DSC, X-ray diffraction and Raman scattering. They can be coherently interpreted through the possible occurrence of a glassy state; on the other hand they enable us to anticipate shortly a microscopic description of this phase selectively based on the molecular orientations. (5 refs.)

71883 Glass-forming ability of the melt-quenched $(Fe_{1-y}Ni_y)_3B$ alloys. Y.Khan, V.Geiss (Inst. fur Werkstoffe der Elektrotechn., Ruhr-Univ. Bochum, Bochum, Germany).
Z. Metallkd. (Germany), vol.74, no.5, p.317-18 (May 1983).
Glass-forming ability of the $(Fe_{1-y}Ni_y)_3B$ alloys obtained by quenching from the melt has been investigated. This is found to be fair in the composition range $0 \leq y \leq 0.40$, i.e, the alloys in this composition range could easily be melt-quenched into the glassy state. For $y > 0.40$, the glass-forming ability is poor depending upon the value of y. Thermal analyses of the master alloy melts have revealed that the glass-forming ability of the $(Fe_{1-y}Ni_y)_3B$ alloys scales inversely with the degree of undercooling of the melts, i.e., the higher the undercooling of the alloy melt, the lower the glass-forming ability of that alloy. 61.40D Glasses

71884 The structure of $Fe_{0.8}B_{0.2-x}Si_x$ metallic glasses. L.Dargel-Sulir, M.Pyka, A.Kozlowski (Inst. of Metall., Acad. of Mining & Metallurgy, Cracow, Poland).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.435-43 (April 1983).
Structure of $Fe_{0.8}B_{0.2-x}Si_x$ metallic glasses was determined from the radial distribution function (RDF) obtained by X-ray technique, with $x=0$, 0.06 and 0.10. An attempt was made to analyze the effect of Si contents on the structure of the glasses. (14 refs.)

71885 New soft magnetic materials. B.de Ronzyova, P.Butvin, P.Duhaj.
Elektrotech. Obz. (Czechoslovakia), vol.72, no.4, p.212-16 (April 1983). In Czech.
The paper deals with some magnetic properties of amorphous metallic alloys. Besides interesting physical problems, e.g. ferromagnetism of non-crystalline solids these materials also offer significant industrial applications, namely as soft magnetic materials. Metal-metalloid alloys called metallic glasses are in principle easy to prepare and possess high permeability, low coercivity, low power losses which often suffer no deterioration upon mechanical strain. The stress is put on low magnetostrictive cobalt metallic glasses produced at the Institute of Physics of EPRC SAS in Bratislava. Experimental data concerning several magnetic properties as well as the use of metallic glasses for magnetic shielding are reported in some detail. (8 refs.)

71886 IR spectra and structures of tellurite glasses. Y.Dimitriev, V.Dimitrov (Higher Inst. of Chem. Technol., Sofia, Bulgaria), M.Arnaudov.
J. Mater. Sci. (GB), vol.18, no.5, p.1853-8 (May 1983).
It is shown with IR spectral investigations that the short range order of certain tellurite glasses, obtained from monomineral crystalline phases, is similar to that of the crystals. They may contain the following polyhedra: TeO_4-trigonal bipyramids (C_{2v} symmetry), deformed TeO_4 groups, TeO_3 trigonal pyramids (C_{3v} point symmetry), or combinations of these polyhedra. The introduction of V_2O_5 and MoO_3 in the binary glasses leads to a $TeO_4 \rightarrow TeO_3$ transition. MoO_3 delays the decay of TeO_4 groups in a wider concentration range. (17 refs.)

71887 Thermally activated crystallization of $(GeSe_2)_{70}(Sb_2Te_3)_{20}(GeTe)_{10}$ alloy glass: morphological and calorimetric study. M.T.Clavaguera-Mora, S.Sunrinach, M.D.Baro, N.Clavaguera (Dept. de Termologia, Univ. Autonoma de Barcelona, Barcelona, Spain).
J. Mater. Sci. (GB), vol.18, no.5, p.1381-8 (May 1983).
The rate of crystallization of $(GeSe_2)_{70}(Sb_2Te_3)_{20}(GeTe)_{10}$ vitreous samples was investigated by means of differential scanning calorimetry. Crystallization proceeds in two stages. The activation energy of each stage of crystallization was determined. The evolution of the microstructure during crystallization was investigated by X-ray analysis and optical and scanning electron microscopy. Crystalline nuclei emerge in the bulk and develop in a spherulitic form. A lamellar structure is clearly observed when crystallization is completed. (17 refs.)

71888 A new family of tellurite glasses. I. Glass formation. V.Kozhukharov, M.Marinov, I.Gugov (Inst. of Chem. Technol., Sofia, Bulgaria), H.Burger, W.Vogel.
J. Mater. Sci. (GB), vol.18, no.5, p.1557-63 (May 1983).
Glass formation in three-component tellurite-phosphate and tellurite-borate vitreous systems has been determined, with the latter including metal oxides or metal halides (chloride, fluoride or bromide), respectively. The results obtained have served as a base for the determination of the glass forming tendency in a number of tellurite-metaphosphate and tellurite-metaborate triple combinations. Hence a new family of tellurite glasses has been obtained. It has been established that the glass formation is most observed in alkaline, earth alkaline oxide and halide metaphosphate systems. The three-component tellurite-metaphosphate and metaborate systems investigated have been treated as partial three-component sections of the main four-component tellurite-phosphate and tellurite-borate systems also. (36 refs.)

71889 Kinetics of crystallization of ZrF_4-BaF_2-LaF_3 glass by differential scanning calorimetry. N.P.Bansal, R.H.Doremus, A.J.Bruce, C.T.Moynihan (Materials Engng. Dept., Rensselaer Polytech. Inst., Troy, NY, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.233-8 (April 1983).
The kinetics of devitrification in ZrF_4-BaF_2-LaF_3(62-33-5 mol%) glass were studied by isothermal and nonisothermal methods using differential scanning calorimetry. The crystallization reaction followed the Avrami equation, $x=1-\exp[-(kt)^n]$, where x is the fraction crystallized after time t. The rate constant k obeyed an Arrhenius equation. The value of the Avrami exponent, n, was 3.2 ± 0.2, indicating three-dimensional crystal growth at a constant number of nucleation sites. Values of kinetics parameters obtained from isothermal and nonisothermal techniques were in excellent agreement. The heat of crystallization measured from isothermal peaks was computed to be 38.5 ± 3.5 J/g. (28 refs.)

71890 Network structure of sodium and potassium borosilicate glass systems. K.Takahashi, A.Osaka (Dept. of Industrial Chem., Okayama Univ., Okayama, Japan), R.Furuno.
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.15-26 (April 1983).
Molar volumes and optical absorption spectra of Ni^{2+} ions were measured for sodium and potassium borosilicate glasses of the compositions $xR_2O.B_2O_3.rSiO_2$($0.01<x<2.0$; $r=1$ and 2), where parameters x and r represent respectively the molar ratios R_2O/B_2O_3 and SiO_2/B_2O_3. The presence of structural groups was discussed from the results. It was confirmed that addition of an alkali oxide changed BO_3 units to RBO_4 units in the range $x<0.55$ for $r=1$ and $x<0.6$ for $r=2$, while it created $ROSiO_3$ units in the range $0.55<x<0.8$ for $r=1$ and $0.6<x<0.9$ for $r=2$. In the range $x>0.8$ for $r=1$ and $x>0.9$ for $r=2$, $ROSiO_3$ and $ROBO_2$ units were created by the alkali addition. Here $ROBO_2$ units were also formed as a result of self-decomposition of RBO_4 units. The volume of void associated with a BO_4 unit was calculated and compared with the size of sodium and potassium ions. It was shown that sodium ions were small enough to be accommodated in the void whereas potassium ions were too large. This could explain the composition dependence of the molar volume of the sodium and potassium borosilicate glasses in the composition range $x<0.55$ for $r=1$ and $x<0.6$ for $r=2$. (21 refs.)

71891 Investigation of TiO_2-SiO_2 glasses by X-ray absorption spectroscopy. R.B.Greegor, F.W.Lytle (Boeing Co., Seattle, WA, USA), D.R.Sandstrom, J.Wong, P.Schultz.
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.27-43 (April 1983).
The coordination and nearest-neighbor bond distances of Ti in a series of TiO_2-SiO_2 glasses have been quantitatively determined using a combination of XANES and EXAFS measurements about the Ti K-edge at 4966 eV. The glasses covering the range 0.012 to 14.7 wt.% TiO_2 were prepared by flame hydrolysis of predetermined mixtures of $SiCl_4$ and $TiCl_4$ vapors. At TiO_2 concentrations below $\sim$0.05 wt.%, Ti is found in a rutile-like octahedral coordination. With increased TiO_2 content in the glass, a two-site model applies in which Ti is found predominately in a fourfold site. About $\sim$9 wt.% TiO_2, the sixfold/fourfold ratio increases appreciably and eventually at $\sim$15 wt.% TiO_2, crystalline TiO_2 segregates out as a second phase. The average Ti-O-Si bond angle in these glasses was estimated to be $\sim$159° which is slightly larger than the most probable value of 152 degrees of Si-O-Si in vitreous SiO_2. Within the accuracy of the edge shift measurements all Ti in the glass is in 4+ valence. Finally, various physical properties such as density, optical transparency and thermal expansion are correlated in light of the new structural data for this interesting binary silicate glass system. (27 refs.)

71892 Thermodynamical interpretation of the structural and enthalpic properties of the crystallization of the Fe-B glasses. C.Cunat, M.Notin, J.Hertz (Lab. de Thermodynamique Metall., Univ. de Nancy I, Vandoeuvre-les-Nancy, France), J.M.Dubois, G.Le Caer.
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.45-60 (April 1983).
The crystallization of melt quenched $Fe_{1-x}B_x$ glasses has been studied by means of differential enthalpic analysis. The crystallization enthalpies show that a phase separation at a microscopic scale prevails in the glasses with $x<0.2$, in agreement with the authors' previous Mossbauer results. The origin of this micro-phase separation is discussed. A tentative description of the thermodynamical properties of these glasses is proposed on the basis of their measurements and of the published data for the pure elements. (38 refs.)

71893 Study of sodium silicate melt and glass by infrared reflectance spectroscopy. F.Domine, B.Piriou (Lab. des Elements de Transition dans les Solides, CNRS, Meudon-Bellevue, France).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.125-30 (April 1983).
Infrared reflectance spectra and the derived absorption spectra of a Na_2O-1.41 SiO_2 glass and of the parent melt are reported. Polymers with 2 bridging oxygens per silicon (chains) and 3 bridging oxygens (sheets) are identified. Spectra of glass and melt are qualitatively similar. Melt absorption bands show a 10-30 cm^{-1} shift to lower frequencies. They are broader and less intense than those of the glass which does not agree with Sweet and White's reflectance measurements (1969) on similar glass and melt. The small differences between glass and melt can be attributed to the thermal expansion of the medium. (14 refs.)

71894 Structure analysis of $MgSiO_3$ glass. C.D.Yin, M.Okuno, H.Morikawa, F.Marumo (Res. Lab. of Engng. Materials, Tokyo Inst. of Technol., Yokohama, Japan).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.131-41 (April 1983).
The structure of $MgSiO_3$ glass was investigated by a combination of radial distribution function (RDF) analysis with an intensity comparison method on the basis of X-ray diffraction data. There appeared five peaks at 1.63, 2.08, 2.58, 3.25 and 4.2 Å in the RDF curve. The short range structure was found to be similar to that observed in pyroxenes: single chains composed of SiO_4 tetrahedra are linked by Mg^{2+} ions laterally. The Mg^{2+} ion is surrounded by six oxygen atoms on average, four of which form Mg-O pairs with an average distance of 2.08 Å and the remainder Mg-O pairs of 2.50 Å which contribute to the formation of the third peak at 2.58 Å in the RDF curve together with the O-O pairs (2.66 Å) in SiO_4 tetrahedra. The calculated intensity curve based on this model was in good agreement with the observed one. (21 refs.)

71895 New halide glasses—bromide glasses based on $ZnBr_2$. I. Vitreous zinc bromide. Hefang Hu, Fuding Ma, J.D.Mackenzie (Dept. of Materials Sci. & Engng., Univ. of California, Los Angeles, CA, USA).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.169-72 (April 1983).
The preparation and several physical properties of $ZnBr_2$ glass are presented. The glass transition temperature and the crystallization temperature were measured by DTA with a heating rate of 7.5°C/min under a flowing nitrogen atmosphere. The density of the glass was measured by a pycnometer method using hexane as a working liquid and found to be 3.77 g/cm^3. The infrared absorption spectra in the region of 4000-250 cm^{-1} were recorded using a Perkin-Elmer 457 type double beam, grating spectrophotometer. (12 refs.)

71896 Chemical short-range order and phase separation in Pr-Ga-Fe glasses. J.G.Zhao, S.G.Cornelison, D.J.Sellmyer (Behlen Lab. of Phys., Univ. of Nebraska, Lincoln, NE, USA), G.Hadjipanayis.
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.203-7 (May 1983).
The authors present X-ray diffraction and selected-area-electron diffraction and fluorescence measurements of $(Pr_{80}Ga_{20})_{100-x}Fe_x$ amorphous alloys for $0\leq x\leq 30$. Partial pair-distributions were determined and compared with calculations based on a random-occupation model. The results show that the atomic distribution is not random. The selected-area electron diffraction and fluorescence results for $x\gtrsim 20$ show the presence of a separation into Fe-rich and Fe-poor glassy phases. This phase separation plays an important role in the magnetic properties of the alloys. (7 refs.)

71897 Fast two-level systems in vitreous silica. T.Geszti (Res. Inst. for Tech. Phys., Hungarian Acad. of Sci., Budapest, Hungary).
J. Phys. Colloq. (France), vol.43, no.C-9, p.481-4 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
A model containing an extra species of tunneling two-level systems, characterized by a lower threshold 0.3K of the tunneling matrix elements, a coupling constant 0.17 eV for interaction with longitudinal sound waves, and two more parameters for the shape of their distribution function, can account for the temperature dependences of fast specific heat, thermal conductivity, sound absorption and sound velocity in vitreous silica below 2K. About 6.3 GHz, corresponding to the threshold 0.3K, a sharp rise is predicted in the frequency dependence of low-temperature (resonant) sound absorption. (11 refs.)

71898 On the problem of homogeneous nucleation in fluoride glasses. M.Matecki, M.Poulain, J.Lucas (Lab. de Chimie Minerale, Univ. de Rennes, Rennes, France), D.R.MacFarlane, C.A.Angell.
Mater. Res. Bull. (USA), vol.18, no.3, p.293-9 (March 1983).
A technique for determining the conditions under which glasses containing large quantities of fluorides become unstable against homogeneous nucleation during annealing at the glass transition temperature, is described. Its application to a system containing MnF_2, one of the better glass-promoting fluorides, suggests that most fluoride glasses produced to date are unstable against nucleation at their glass transition temperatures. This accounts for the difficulty in fabrication low scattering loss fibers by normal techniques and emphasizes the importance of developing optimized compositions over study of other properties, for this type of application. (17 refs.)

71899 Small volume change on melting as a new criterion for easy formation of metallic glasses. A.R.Yavari (Lab. de Thermodynamique et Phys.-Chimie Metall., Domaine Univ., Saint Martin d'Heres, France).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.165-8 (25 April 1983).
Using a simplified free-volume model with no adjustable parameters, a physical basis is developed for the existing correlation between the ease of glass formation and a small volume increase associated with melting. It is suggested that the fusion volume must be removed by thermal contraction, thus lowering the glass-transition temperature and reducing the stability of the amorphous phase. Furthermore, critical quench rates needed to suppress crystallisation, increase rapidly with fusion volume, as the latter increases atomic diffusivity in the undercooled liquid. (23 refs.)

71900 Compositional effects in Pd-B glassy alloys from X-ray determined radial distributional functions. G.Cocco, L.Schiffini, M.Sampoli (Univ. Venezia, Venezia, Italy), A.Lucci.
Phys. Status Solidi a (Germany), vol.76, no.2, p.753-62 (16 April 1983).
X-ray determined radial distribution functions of amorphous Pd-B alloys are obtained as a function of B content through the glass forming region in the range 24 to 30 at.%. The structure factors are found to exhibit no characteristic shoulder in the second halo, whereas the correlation functions show the subpeak height ratio of the second peak splitting reversed as compared with that of the generality of metal-metalloid glassy alloys. The experimental results are discussed in terms of a model of the dense random packing of hard spheres. Specific chemical interactions are surmised to explain distinguishing features developing in the radial functions of the hypereutectic glasses. (50 refs.)

71901 Nitrogen glasses containing berium. Preparation and properties. P.Verdier, L.Cohen, S.Mariotti, R.Marchand (Lab. de Chimie Minerale, Univ. de Rennes I, Rennes, France).
Rev. Chim. Miner. (France), vol.20, no.1, p.1-8 (1983). In French.
Nitrogen glasses have been prepared in the quinary system Ba-Si-Al-O-N. The influence of the big ion Ba^{2+} and the role of nitrogen have been characterized. In comparison with other systems M-Si-Al-O-N, the vitreous field in the cut BaO-SiO_2-AlN, determined at 1400°C, is more extensive and the glasses are less hard. Density and hardness increase with nitrogen content. The calculation of the anion-gramme number per volume unit and its variation with the ionic radius of M would lead to the glass structure understanding. (10 refs.)

71902 The kinetics of structural relaxation in amorphous $Fe_{40}Ni_{40}P_{14}B_6$. M.E.Sonius, B.J.Thijsse, A.van den Beukel (Lab. of Metall., Delft Univ. of Technol., Delft, Netherlands).
Scr. Metall. (USA), vol.17, no.4, p.545-8 (April 1983).
The slow irreversible increase of the resistivity during structural relaxation of Metglas 2826 can be ascribed to the annealing out of free volume. The kinetics of the process is in agreement with a model proposed by A. van den Beukel and S. Radelaar (see Acta Met., vol.31, no.3, p.419-27, 1983). The effect of the amount of free volume on the ordering rate (CSRO) was also demonstrated in a quantitative way. (9 refs.)

71903 Short range order in $(Ni_{65}Fe_{35})_{77}B_{23}$ metallic glass by neutron diffraction. E.Svab, N.Kroo (Central Res. Inst. for Phys., Budapest, Hungary), S.N.Ishmaev, I.P.Sadikov, A.A.Chernyshov.
Solid State Commun. (USA), vol.46, no.4, p.351-3 (April 1983).
The $S(Q)$ structure factor of $(Ni_{65}Fe_{35})_{77}B_{23}$ metallic glass was measured by time-of-flight neutron diffraction up to 24 $Å^{-1}$ momentum transfer. The distribution of transition metal-boron and transition metal-transition metal first neighbour atom pairs is resolved in the distribution function obtained from $S(Q)$ by Fourier transformation. The distances of these first neighbours pairs, the width of their distribution, the partial coordination numbers and the short range order parameter are given. The results on $(Ni_{65}Fe_{35})_{77}B_{23}$ and on the previously studied $Fe_{81}B_{10}$ amorphous alloys are compared. (10 refs.)

71904 Crystallization mechanism in glasses of MnO-P_2O_5 series. D.Miyazaki, Y.Hakamatsuka, T.Tsuchiya (Faculty of Sci. & Technol., Sci. Univ. of Tokyo, Noda-shi, Japan).
Yogyo-Kyokai-Shi (Japan), vol.91, no.3, p.103-9 (1983). In Japanese.
The crystallization mechanism in the glasses of MnO-P_2O_5 series containing from 35 to 50 mol.% MnO has been investigated by high temperature microscope, X-ray diffraction and scanning electron microscopy (SEM) techniques. Each batch was melted for 30 minutes at 1150°C in air. Two kinds of specimens were prepared. The melts were poured onto a stainless plate to form discs for specimens of 50 mm diameter. After annealing, polished bulk specimens of 10 mm thickness were prepared for the experiments of crystallisation. The blown-films (about 10 μm thickness) were prepared from the melts for the experiments of high temperature microscope. Each bulk specimen was covered with a stainless cup and heated in the electric furnace, under the condition of uniform temperature distribution. Each crystallization temperature was determined by DTA method. The precipitated crystals were determined by X-ray diffraction analysis to be mainly manganese pyrophosphate ($Mn_2P_2O_7$). The specimens containing $35\sim45$ mol.% MnO from SEM on the fractured surface showed a fiber-oriented structure due to one-dimensional crystal growth from the surface toward the interior. (16 refs.)

71905 Microstructures of glassy and metastable crystalline phases formed from Fe-C ternary alloys. E.Hornbogen, I.Schmidt (Inst. fur Werkstoffe, Ruhr-Univ. Bochum, Bochum, Germany).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.199-204
Fe-C-base alloys were rapidly cooled from the liquid and then reheated from ambient temperature. In addition to the transition metal elements (V,Cr,Mo,W), B was added as a third element to substitute C. A systematic approach to the understanding of phase and microstructures, which form under these conditions is the purpose of this work. This includes the considerations of forming ability and thermal stability of metallic glasses. Three aspects require attention: (a) absolute stability of the glass phase, (b) relative stability i.e. the difference of free energy between the amorphous and particular crystalline phases, (c) kinetic stability based on the rate and mechanisms of crystallization reactions including the rate determining diffusion process. Light and electron microscopy and electron diffraction were used for the analysis of the structure of the alloys. (7 refs.)

71906 Microstructure of semi-crystalline thermoplastics structural foams. R.H.Burton, P.R.Hornsby (Dept. of Non-Metallic Materials, Brunel Univ., Uxbridge, England).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.195-6 (May 1983).
As part of a wider investigation concerned with the processing and structural factors affecting the performance of reinforced and unmodified variants of these materials, a detailed examination has been made of the morphology within the cells of structural foam polypropylene. This is prepared by a low-pressure short-shot injection moulding process using a premix of polymer and chemical blowing agent. (3 refs.)

71907 FTIR evidence of β crystal phase formation in PVDF/PMMA blends. C.Leonard, J.L.Halary, L.Monnerie (Lab. PCSM Ecole Superieure de Phys. et Chimie Industrielles de la Ville de Paris, Paris, France).
Polym. Commun. (GB), vol.24, no.4, p.110-14 (April 1983).
Blending of PVDF with PMMA in relative amounts of around 70-30 wt.% may lead directly to the β-crystal from the PVDF, provided the blend is quenched from the melt and then annealed in the temperature range 330-390K. This important result, the interest of which is related to the piezoelectric properties of the β form of PVDF, is mainly suported by FTIR (Fourier transform infra-red) analysis focused on crystal phase nature and crystallization kinetics. (8 refs.)

71908 Local order in amorphous polystyrenes: a high-resolution ^{13}C-NMR study. J.R.Havens, J.L.Koenig (Case Western Reserve Univ., Cleveland, OH, USA).
J. Polym. Sci. Polym. Lett. Ed. (USA), vol.21, no.4, p.243-7 (April 1983).
The authors report a preliminary investigation of local order in amorphous polystyrenes with recently developed high-resolution ^{13}C-NMR techniques for solids. Samples of atactic polystyrene were chosen for two reasons: (1) They form a completely noncrystalline glass when cooled isobarically from the melt; (2) laser light scattering data have been recorded for these samples and suggest increased chain ordering as the pressure under which the sample is cooled increases (1). One way to detect the order which may exist in these materials is to monitor the localized motion of the polymer chains. Such dynamic information can be obtained through high-resolution solid-state ^{13}C-NMR. An advantage of this technique is its ability to distinguish among molecular motions in various segments of the polymer chain; for example, side chain and main chain motion can be separated spectroscopically. (14 refs.)

71909 Single-chain scattering in heterogeneous block copolymers. F.S.Bates, C.V.Berney, R.E.Cohen (Dept. of Chem. Engng., MIT, Cambridge, MA, USA), G.D.Wignall.
Polymer (GB), vol.24, no.5, p.519-24 (May 1983).
Diblock copolymers consisting of polystyrene (S) attached to a polybutadiene (B) block (which is either hydrogenous or perdeuterated) have been synthesized and blended in such a way that the microphase-separated S and B domains have equal scattering-length densities, thus eliminating the component of small-angle neutron scattering (SANS) due to the domain structure. Two samples were studied: one with small spherical polybutadiene microdomains whose size was in essential agreement with calculations assuming equilibrium, and a second one of larger molecular weight in which the sphere size, while larger, was considerably smaller than predicted from equilibrium theory. The SANS spectra of these samples were analysed to give the radii of gyration R_g and molecular weights M_w of the labelled polybutadiene blocks from plots of I^{-1} versus Q^2 and least-square fits to the single-chain scattering function proposed by Debye. Results for the first sample agreed with the molecular weight obtained from chromatography and UV absorption and with the R_g found in bulk polybutadiene of similar M_w. The SANS estimates of both M_w and R_g for the second sample were anomalously large; these deviations may be due to (a) nonGaussian conformations of the polybutadiene chains imposed by the nonequilibrium state of the microdomain, or (b) clustering of the deuterated polybutadiene chains within the microdomain due to small isotopic differences in chemical potential, enhanced by the larger M_w. Observations on other systems suggest that the second effect is the dominant one. (30 refs.)

71910 Anisotropy of X-ray structural parameters of the three phase model in cellulose I. P.S.Mukherjee, G.B.Mitra (Dept. of Phys., Indian Inst. of Technol., Kharagpur, India).
Polymer (GB), vol.24, no.5, p.525-8 (May 1983).
Anisotropy of X-ray structural parameters of the three phase model proposed by Mitra and Mukherjee (1980) has been investigated in the case of cellulose fibres of ramie, hemp and jute. The structural parameters have been determined separately from each of the observable equatorial reflections. The parameter degree of crystallinity as defined in the model is in fact anisotropic at least in the samples studied. The parameter degree of paracrystallinity introduced by Mitra and Mukherjee was also found to be anisotropic. Several important correlations between the structural parameters have been drawn. It has been observed, in agreement with the recent findings of Hosemann and Balta Calleja (1980) that the greater the paracrystalline distortion, the smaller the 'paracrystallite size'. (10 refs.)

61.50 CRYSTALLINE STATE

(inc. molecular motions in solids; for magnetic structure and spin systems, see 75.25)

71911 Huckel and Mobius boundary conditions for solids and orbital symmetry correlation in the rotational phase transition of molecular crystals. Ying-Nan Chiu (Inst. of Chem., Acad. Sinica, Nankang, Taiwan).
Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.26-30 (6 May 1983).
A new cyclic boundary condition which corresponds to a Mobius strip representation of a one-dimensional crystal is introduced. It is compared with the usual Bloch and Born-von Karman boundary condition which is shown to be a Huckel condition in the sense of LCAO MO treatment of a ring structure. The potential relevance of this Mobius condition to one-dimensional molecular and liquid crystals in which the relative molecular orientation changes during phase transition is alluded to. A comparison of the energies for the twisted and nontwisted form of the linear crystal is derived in the LCAO approximation. The orbital symmetry correlation in the concerted twist of the atomic or molecular orbitals along the linear backbone during a rotational polymorphic structural transition is also derived. (17 refs.)

71912 Neutron scattering study of the reorientational motions in $Cr(CO)_3(\eta^6C_6H_6)$ and $Mn(CO)_3(\eta^5C_5H_5)$. G.Lucazeau, K.Chhor (Lab. Chimie-Phys. du Solide, Univ. Paris-Nord, Villetaneuse, France), C.Sourisseau, A.J.Dianoux.
Chem. Phys. (Netherlands), vol.76, no.2, p.307-14 (15 April 1983).
Incoherent quasi-elastic neutron scattering experiments, using different resolutions and a wide Q range, have been performed on polycrystalline samples of $Cr(CO)_3(\eta^6C_6H_6)$ and $Mn(CO)_3(\eta^5C_5H_5)$ in the 280-320K temperature range. Aromatic rings are involved into a reorientational process characterized by an activation energy of ≈ 16 kJ mol^{-1} and by correlation times of the order of 2×10^{-11} s and 5×10^{-11} s at 300K for C_6H_6 and C_5H_5 rings respectively. Experimental elastic incoherent structure factors are in agreement with the $2\pi/6$ and $2\pi/5$ jump models and the fitted spectra confirm these models. From a comparison with heat-capacity results the authors conclude that $M(CO)_3$ groups are fixed during the reorientational process. Finally a comparison with literature data is presented. (23 refs.)

71913 Dielectric evidence for existence of two-level-systems in cyclohexanol, a 'glassy crystal' system. G.P.Singh (Max-Planck Inst. fur Festkorperforschung, Stuttgart, Germany), R.Vacher, R.Calemczuk.
J. Phys. Colloq. (France), vol.43, no.C-9, p.525-7 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
Cyclohexanol exhibits a 'glassy' crystal phase at low temperatures. In this phase the mass centers of the molecules form a crystalline lattice, but the orientations of the molecules are disordered. The authors have measured the dielectric constant of these crystals in temperature range 0.4K to 20K at a frequency of 11 GHz. At low temperatures the dielectric constant decreases logarithmically with temperature and increases again at higher temperatures. This behaviour is similar to the low temperature dielectric behaviour of amorphous dielectrics with spatial disorder and may be interpreted in terms of existence of two-level systems with a constant density of states. Examination of two samples with different water contents shows that the water does not have any significant influence on the density of states and transverse dipole moment of the two-level-systems. (8 refs.)

71914 The effect of the microscopic structure on formation of characteristic layered inclusions in the single crystal of potassium acid phthalate (KAP). Zhao Qing-lan, Chen Jin-zhang, Huang Yi-sen (Fujian Inst. of the Structure of Matter, Acad. Sinica, Fuzhou, China).
Acta Phys. Sin. (China), vol.32, no.3, p.294-300 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
The formation of characteristic layered inclusions in the single crystal of potassium acid phthalate (KAP) is discussed in view of the effect of its microscopic structure. That three types of microstructural channels trap the impurities or other different phase precipitates in solution, via a special pair of the conical planes with the highest growth rate and the fluctuation of the growth conditions in liquor, is the main mechanism of inclusion formation.

The above argument is in fair agreement with the experimental results for real crystals. (9 refs.)

71915 Convection in melt growth—theory and experiments. N.Kobayashi (Dept. of Appl. Phys., Toyama Univ., Takaoka, Japan).
Oyo Buturi (Japan), vol.51, no.11, p.1206-15 (Nov. 1982). In Japanese. [received: March 1983]
Recently it has become possible using transparent melts to simulate convection by computer and to use simulation results to control melt growth. The use of uplift methods to control melt growth and to achieve a high quality crystal is central to this whole process. Natural and forced convection and mixed convection in TeO_2, $Pb_5Ge_3O_{11}$, $Y_3Al_5O_{12}$, $Gd_3Ga_5O_{12}$ and $Dy_3Al_3O_{12}$ are reviewed. (76 refs.) *M.O.*

71918 Configurations in crystals, rod lattices, and lamellar systems. H.-R.Trebin (Inst. fur Theoretische Phys., Univ. Regensburg, Regensburg, Germany).
Phys. Rev. Lett. (USA), vol.50, no.18, p.1381-4 (2 May 1983).
For three-dimensional ordered media of periodic and partially periodic structure, homotopy theory allows the existence of nonsingular stable distortion fields, which are finite in size and thus resemble extended particles. It is shown that because of integrability conditions homotopy arguments are not adequate for these systems. By methods of differential topology, it is proved that in three dimensions topological particles of this type are unstable, but that there are analogous fields in higher dimensions that cannot decay to a uniform ground state. 71919 Thermal-field rearrangement of faces at the tips of silicon points. P.G.Borzyak, A.A.Dadykin (Inst. of Phys., Acad. of Sci., Ukrainian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.67-70 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1288-91 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors use field emission microscopy to study the change in shape of monocrystalline semiconductor points under the influence of temperature and electric field. They measure the field-emission current from small areas of the tip and to obtain the surface distribution, and then to employ these data to obtain information on changes in shape. By using images obtained from a scanning electron microscope, it was possible to directly determine the dimensions of the crystalline faces and their changes. (4 refs.)

71920 Modification of the pair approximation of the quasi-chemical ordering theory of binary systems. V.A.Klimenko (Faculty of Math., Ural Polytech. Inst., Sverdlovsk, USSR).
Phys. Status Solidi a (Germany), vol.76, no.1, p.42-55 (16 March 1983).
A modified pair variant of the quasi-chemical ordering theory of binary systems is constructed. It is shown that the proposed approximation gives the satisfactory description of the first-order phase transition in the binary alloys with the FCC lattice. A comparison is made of the results received for the temperature changing of the long order parameter with the experiment and results of cluster variation method, where tetrahedrons represent the initial clusters. The application of the proposed method to the alloys with BCC-lattice leads, as it is in the ordinary pair variation of the quasi-chemical approximation, to the known result, that the order-disorder transition in these systems takes place as a second-order phase transition. The connection between the proposed variant of the quasi-chemical theory and the Bragg-Williams-Gorsky ordering theory is established. (36 refs.)

71921 Variable anion polarisability in ionic crystals. G.Raghurama (Dept. of Phys., Indian Inst. of Sci., Bangalore, India), R.Narayan.
Curr. Sci. (India), vol.52, no.5, p.210-12 (5 March 1983).
The authors use an empirical relation to re-estimate the polarisabilities of ions in the alkali halide and alkaline earth chalcogenide crystals. They assume a constant polarisability for cations in line with the results of Mahan (1980), while for the anions they propose a specific dependence on the interionic distance. (15 refs.)

71922 Long-range Van der Waals forces between restricted-dimensional metals. Swee Lian Tan, P.W.Anderson (Bell Labs., Murray Hill, NJ, USA).
Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.23-5 (6 May 1983).
Long-range Van der Waals interactions have been studied in low-dimensional metals such as graphite and polyacetylene. These forces are qualitatively and quantitatively different from the sum of the usual $1/r^6$ dispersion forces. (14 refs.)

71923 Lattice energy of alkali halide crystals. R.B.Yadav (Phys. Dept., Memorial Univ. of Newfoundland, St. John's Newfoundland, Canada).
Solid State Commun. (USA), vol.46, no.4, p.341-2 (April 1983).
A new repulsive term in the ionic interaction potential, $\psi(r) = Ar^{-n}e^{-r/\lambda}$, is suggested and the three unknown parameters A, λ and n are evaluated. Lattice energies of alkali halide crystals are calculated using this form. The results agree fairly well with the experimental values. (10 refs.)

71924 Lamellar morphology and inner structure of crystalline carbyne fragments. V.M.Melnitchenko, B.N.Smirnov, V.P.Varlakov, Yu.N.Nikulin, A.M.Sladkov (A.N. Nesmeyanov Inst. of Organo-Element Compounds, Acad. of Sci., Moscow, USSR).
Carbon (GB), vol.21, no.2, p.131-3 (1983).
By means of transmission scanning electron microscopy and electron diffraction the morphology and the inner structure of crystalline carbyne fragments have been studied. The crystalline specimens of carbyne have been obtained by free vaporization in the arc of spectroscopically pure carbon and the subsequent condensation in vacuo on a freshly sliced rock salt crystal. The basic morphological unit has been shown to appear as a thin transparent platelet (lamel) of ~100 Å of thickness. (16 refs.)

71925 Structure factors for electrons of chromium and iron determined from double refraction effect in electron diffraction. K.Fujita (Coll. of Technol., Kyoto Tech. Univ., Kyoto, Japan).
Mem. Fac. Ind. Arts Kyoto Tech. Univ. Sci. & Technol. (Japan), vol.31, p.72-82 (Dec. 1982). [received: May 1983]
Fine polyhedral particles of chromium (cube) and iron (rhombic dodecahedron) were prepared by evaporating metals in argon gas at a low pressure (Kimoto et al., 1963). An electron diffraction spot from these particles split into a multiplet due to a double refraction effect, as was observed for the cubic particles of magnesium oxide. By analyzing the multiplets, mean inner potential V_0 and Fourier coefficient V_h of chromium and iron were determined. In the case of iron no effect of magnetization of multiplets was detected. (15 refs.)

71926 Symmetry analysis of α-U by neutron diffraction. J.C.Marmeggi (Lab. de Cristallographie, CNS, Grenoble, France).
Solid State Commun. (USA), vol.46, no.4, p.277-81 (April 1983). In French.
Using polycrystalline samples of α-U, careful experiments yield precise neutron diffractograms, taking advantage of a linear multiwire detector. The authors could refine profile and integrated intensities of very weak satellite reflections of first and for some of them of second order. The modulated structure is re-examined. The structure at room temperature may be noncentred. (19 refs.)

71927 Stability and lattice contraction of small platinum particles. S.N.Khanna, J.P.Bucher, J.Buttet (Inst. de Phys. Experimentale, Ecole Polytech. Federale, Lausanne, Switzerland), F.Cyrot-Lackmann.
Surf. Sci. (Netherlands), vol.127, no.1, p.165-74 (April 1983).
The structural stability of Pt clusters of cuboctahedral and icosahedral shapes has been analytically studied by taking an approximation based on the second moment of the density of states to calculate the cohesive energy. The predictions of this model are in agreement with the phenomenological ideas of Ino's (1969) model and the known experimental results for the transition from cuboctahedral to icosahedral geometrical structure. The agreement between the calculated values for the contraction of the interatomic distance as a function of decreasing size, and very recent experimental results is excellent. (19 refs.)

61.55H Alloys

71928 On a new ternary arsenide $NiNbAs_2$: structure and properties. El Houssine el Ghadraoui, R.Guerin, J.Padiou, M.Sergent (Univ. de Rennes-Beaulieu, Rennes, France).

C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.8, p.617-20 (28 Feb. 1983). In French.

$NiNbAs_2$ is orthorhombic, with space group Pnma and unit cell parameters a=5.624 (3), b=3.510 (1), c=12.496 (6) Å. The structure refined by full-matrix least-squares down R=0.061 (R_ω;0.075) is isostructural with those of $NiNbP_2$ and $NiTaP_2$. Magnetic and electrical measurements exhibit the metallic behavior of this new arsenide. (6 refs.)

71929 Crystal structure and magnetic state of pseudobinary intermetallic compounds $Ho(Co_{1-x}Ni_x)_5$. V.V.Chuev, V.V.Kelarev, A.N.Pirogov, S.K.Sidorov, V.S.Koryakova (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).

Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.510-19 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*

Neutron and X-ray diffraction methods were used in the range 1.8-1000K to study intermetallic compounds belonging to the $Ho(Co_{1-x}Ni_x)_5$ system. The crystal structure was determined for two series of samples with the compositions $HoCo_{5.5-5.5x}Ni_{5x}$ and $HoCo_{5-5x}Ni_{5x}$. It was found that the Ni atoms occupied preferentially the $2c$ positions, whereas the Co atoms occupied the $3g$ positions; the coordinates of the atoms were determined more accurately and also the occupancy of the positions in the $TbCu_7$ structure. An analysis of the magnetic structure was made and the orientations of the magnetic moments were found relative to the crystallographic axes. A magnetic phase diagram was plotted. The composition dependences of the sublattice magnetizations $M_{Ho}(x)$, $M(d_{2c})(x)$, and $M(d_{3g})(x)$ were determined. (26 refs.) *A.T.*

71930 The structure of Cr-Al alloys exhibiting anomalous physical properties. S.V.Sudareva, V.A.Rassokhin, A.F.Prekul (Inst. of Metal Phys., Acad. of Sci., Sverdlovsk, USSR).

Phys. Status Solidi a (Germany), vol.76, no.1, p.101-6 (16 March 1983).

An electron diffraction study is made of a quenched Cr-25 at.% Al alloy exhibiting anomalous physical properties. An intensive diffuse scattering, complicated in form, with intensity maxima belonging to the ordered β-phase (Cr_2Al) and the recently observed x-phase is detected. The diffuse scattering, including intensity maxima from the β- and x-phases, is prone to vanish regularly, namely the zero-intensity line is always perpendicular to the reciprocal-space vector, and this indicates that the scattering arises from transversely polarized 'soft' modes. An analysis of the reciprocal lattice of Cr-Al alloys permits the conclusion that the diffraction picture produced by the x-phase may be described by the incommensurate ω-phase known in the literature. The detected structure qualitatively explains anomalies in the physical properties of Cr-Al alloys. (13 refs.)

71931 A comparative analysis of the ordering kinetic laws for the derivation of the vacancy mobility parameters in concentrated alloys. E.Balanzat, M.Halbwachs (Dept. de Recherche Fondamentale, CENG, Grenoble, France).

Phys. Status Solidi a (Germany), vol.76, no.2, p.667-73 (16 April 1983).

It is shown that, under particular experimental conditions, the use of chemical kinetics to analyse the time evolution of short range order may lead to activation energies significantly different from the ones obtained by assuming a spectrum of ordering rates. Reanalysis of previous results in a Ag-8.75 at.% Zn alloy indicates that the latter approach yields energy values in close agreement with the ones obtained by determination methods non based on ordering kinetic considerations, while the former leads, in this specific case, to results at variance with 'best' values. It is concluded that a proper analysis of ordering kinetics has to take into account the inherent existence of a distribution of ordering rates. (17 refs.)

71932 The atomic structure of $(Mn_{1-x}Cr_x)_5Si_3$ and $(Mn_{1-y}Fe_y)_5Si_3$ solid solutions. E.N.Babanova, P.V.Gel'd, Z.A.Istomina, N.I.Sychev.

Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.567-70 (April 1983). In Russian.

X-ray and neutron diffraction investigations have been performed for $(Mn_{1-x}Cr_x)_5Si_3$, $0 \leq x \leq 0.2$, and $(Mn_{1-y}Fe_y)_5Si_3$, $0 \leq y \leq 0.2$, alloys at 293K. It is found that Fe replaces Mn in the $4d$ positions and Cr replaces Mn in the $4d$ and $6g$ positions equally. The impurity atoms in the $4d$ positions form the ordering structure. (3 refs.)

61.60 SPECIFIC STRUCTURE OF INORGANIC COMPOUNDS

71933 Crystal structures of several silicon carbide polytypes belonging to a special structure family. Guo Chang-lin (Shanghai Inst. of Ceramics, Shanghai, China).

Chin. Phys. (USA), vol.3, no.1, p.54-64 (Jan.-March 1983). [received: May 1983]

Silicon carbide is a typical layered compound with over 150 known polytypes. The author has developed a special Laue method, which can be effectively used to determine polytypes, and 85 new polytypes of SiC were found. Oscillation and Weissenberg methods were used to determine the structures of these new polytypes without success due to the presence of diffraction spots of basic polytypes $6H$, $15R$, and $8H$ in these photographs. This is due possibly to the small size of the new polytypes in bulk crystals, and also due to the fact that these new polytypes are embedded in large $6H$, $8H$, and $15R$ polytypes. A modified Laue method for determining the crystal structures of SiC polytypes was developed, as well as a method for calculating the diffracion intensities of the Laue spots. The calculation of the structure factor F_{hkl} in $[(33)_m32]_3$, $[(33)_m34]_3$, $[(22)_m23]_3$, and $[(44)_m43]_3$ structure families was simplified. By using this method, the crystal structures of 9 new polytypes of SiC were determined. These structures, designated by the Z stacking sequences (Zhdanov notation), are $231R$: $[(33)_{12}32]_3$, $249R$: $[(33)_{13}32]_3$, $321R$: $[(33)_{17}32]_3$, $339R$: $[(33)_{18}32]_3$, $237R$: $[(33)_{12}34]_3$, $417R$: $[(33)_{22}32]_3$, $453R$: $[(33)_{24}34]_3$, $93R$: $[(44)_3 43]_3$, $261R$; $[(44)_{10}43]_3$. (27 refs.)

71934 The alkaline earth hydrogen fluorides $SrF(HF_2)$ and $BaF(HF_2)$ [crystal structure]. W.Massa, E.Herdtweck (Fachbereich Chem., Univ. Marburg, Marburg, Germany).

Acta Crystallogr. Sect. C (Denmark), vol.C39, pt.5, p.509-12 (15 May 1983). In German.

$SrF(HF_2)$, monoclinic, $P2_1/m$, $a=7.097$ (1), $b=3.942$ (1), $c=4.851$ (1) Å, $\beta=117.63$ (1)°, $Z=2$, $D_x=4.022$ g cm^{-3}, $V=120.24$ Å^3, μ(Mo $K\alpha$)=219.1 cm^{-1}, 621 reflections, $R_w=0.029$, $F(000)=132$. $BaF(HF_2)$, isotypic, $a=7.300$ (1), $b=4.312$ (1), $c=4.990$ (1) Å, $\beta=115.52$ (1)°, $Z=2$, $D_x=4.576$ g cm^{-3}, $V=141.75$ Å^3, μ(Mo $K\alpha$)=130.4 cm^{-1}, 675 reflections, $R_w=0.016$, $F(000)=168$. Single crystals of $SrF(HF_2)$ and $BaF(HF_2)$ have been obtained by hydrothermal high-pressure synthesis (3GPa, 573K). Their crystal structures were determined by X-ray diffractometry at 298K. The alkaline-earth ions show tricapped trigonal prismatic coordination formed by four F^- and five $[FHF]^-$ anions. As a result of the characteristic three-dimensional connection of these groups different bonding to the Sr(Ba) ions is observed for the two F atoms in the $[FHF]^-$ anions. Bond strength calculations account for asymmetric hydrogen bonds, as has been suggested previously from NMR results, and give the direction of the proton shift. The F-F distances in the $[FHF]^-$ groups corrected for thermal motion are 2.269 Å for the Sr and 2.281 Å for the Ba compound. (22 refs.)

71935 Deformation density in complex anions. IV. Magnesium thiosulfate hexahydrate, $MgS_2O_3.6H_2O$. Y.Elerman, J.E.Bats, H.Fuess (Inst. fur Kristallographie und Mineralogie, Univ. Frankfurt, Frankfurt am Main, Germany).

Acta Crystallogr. Sect. C (Denmark), vol.C39, pt.5, p.515-18 (15 May 1983).

For pt.III see Acta Cryst. B, vol.38, p.2116 (1982). The deformation electron density in $MgS_2O_3.6H_2O$ has been determined at 120K from a combination of X-ray and neutron diffraction data. $M_r=244.56$, $Pnma$, $a=9.324$ (2), $b=14.451$ (4), $c=6.862$ (1) Å, $V=925.2$ (4) Å^3, $Z=4$, $D_x=1.756$ Mg m^{-3}, $F(000)=512$. Neutron diffraction: $\lambda=0.8410$ Å, $(\sin Q/\lambda)_{max}=1.02$ Å^{-1}, $\mu=0.158$ (1) mm^{-1}, $R_w(F)=0.047$ for 2771 independent reflections. X-ray diffraction: Nb-filtered Mo $K\alpha$, $\lambda=0.71069$ Å, $(\sin \theta/\lambda)_{max}=0.85$ Å^{-1}, $\mu=0.655$ mm^{-2}, $R_w(F)=0.026$ for 2489 independent reflections. Peaks of about 0.25 eÅ^{-3} are observed at the midpoints of the S-O and S-S bonds. Extended lone-pair regions up to 0.30 e Å^{-3} are found at the back of the sulfate O atoms. The lone-pair density at the terminal S atom is rather diffuse. All three independent water molecules show O-H bond peaks of 0.35-0.40 e Å^{-3}. Their O lone-pair peaks amount of 0.30-0.37 e Å^{-3} and are considerably extended normal to the HOH plane. (31 refs.)

71936 Synthesis and structure of orthorhombic cadmium platinum oxide, $CdPt_3O_6$. C.T.Prewitt, K.B.Schwartz (Dept. of Earth & Space Sci., State Univ. of New York, Stony Brook, NY, USA), R.D.Shannon.

Acta Crystallogr. Sect. C (Denmark), vol.C39, pt.5, p.519-21 (15 May 1983).

$M_r=793.7$, orthorhombic, $Cmmm$, $a=7.2144$ (6), $b=10.190$ (1), $c=3.1650$ (2) Å, $V=232.67$ (6) Å^3, $Z=2$, $D_x=11.33$ g cm^{-3}, λ(Ag $K\alpha$)=0.5609 Å, $\mu=513.5$ cm^{-1}, $T=293$K, $F(000)=660$, R=0.047 for 417 unrejected reflections in the range $0.0849<\sin \theta/\lambda<0.8914$ Å^{-1}. Crystals of $CdPt_3O_6$ were grown by a hydrothermal technique. Bulk electrical-resistivity measurements on a pellet of compressed powder yielded values of $\rho(298K)=0.03$ Ωm and $E_a=0.04$ eV (1 eV=1.60×10^{-19} J) in the range 5 to 298K. This low resistivity is related to metal-metal distances of 3.165 Å in a structure which includes chains of edge-shared PtO_6 octahedra and columnar stacks of planar PtO_4 groups extending along [001]. (17 refs.)

71937 Identification of polytypes of MX_2-type compounds. II. Structures of 20 new polytypes of cadmium iodide. B.Palosz (Inst. of Phys., Warsaw Tech. Univ., Warszawa, Poland).

Acta Crystallogr. Sect. C (Denmark), vol.C39, pt.5, p.521-8 (15 May 1983).

The identification of polytypes of crystals of MX_2 type using the intensity diagrams of the 10.l and 10.$\bar{l}$ reflexions is discussed. It is shown that these diagrams enable some standardization of the structures of simple polytypes, classifying them into structural series. The structures of 20 new polytypes of CdI_2 obtained from solutions have been determined: $16H_8$: $(t_3)f1of1tf5$; $20H_{12}$: $(t)_5f4(t)_3f5$; $22H_6$: $(t)_7f1f1tf5$; $22H_7$: $(t)_5f2(o)_2f2tf4$; $22H_8$: $tf2(o)_2f2f1f2(t)_2f1f1$; $26H_5$: $(t)_7f2(o)_2f2tf4$; $28H_5$: $(t)_9f4(t)_3f5$; $38H_2$: $(t)_{17}f1f2$; $40H_2$: $(t)_{13}f4(t)_5f5$; $40H_3$: $tf1(o)_2f1(t)_{13}f2f2$; $24R_3$: $f1f1f2f2$; $48R_2$: $f1f1tf2f1(t)_2f5$; $48R_3$: $(t)_4f4(t)_2f5$; $54R_3$: $f1f1f2(o)_3f1tf5$; $66R_1$: $f1f1(t)_5f2f1f2f2$; $66R_2$: $f1f1(t)_5f_2of1f5$; $84R_3$: $f1f1(tf2f1)_2(t)_4f2f2$; $84R_4$: $f1(o)_6f1(t)_4f2f2$; $96R_1$: $(t)_8f4(t)_6f5$; $120R_1$: $(t)_{10}f4(t)_8f5$; 18 already known polytypes have also been recognized. The uniqueness of the structures of polytypes determined by the standard a-axis oscillation method is discussed. (11 refs.)

71938 Density-functional theory for solid nitrogen and carbon dioxide at high pressure. R.LeSar (Los Alamos Nat. Lab., Univ. of California, Los Alamos, NM, USA), R.G.Gordon.

J. Chem. Phys. (USA), vol.78, no.8, p.4991-6 (15 April 1983).

Structural properties of solid N_2 and CO_2 under pressure have been studied with a recently reported theory. The model allows for calculation of the structure and dissociation energy of molecular crystals, using no empirical parameters where dispersion energy is included as a sum of the pair interactions. Comparison with available low temperature experimental results shows good agreement with average errors in lattice constants of about 1% and in lattice energies of about 6%. Calculations were performed on nitrogen in a number of structures, including the experimentally observed $Pa3(\alpha)$, $P4_2/mnm(\gamma)$, $P6_3/mmc(\beta)$, and $Pm3n$ structures, as well as a recently proposed structure with space group $R3m$. The $R3m$ structure was found to be more stable than the $Pa3$ structure at about 10 kbar. Calculations were carried out on carbon dioxide in the $Pa3$ structure. Comparison of the calculated pressure-volume curves with room temperature experimental curves to 100 kbar shows very close agreement for both N_2 and CO_2. (34 refs.)

71939 Inelastic neutron scattering and transmission electron microscope studies of lead dioxide. P.T.Moseley (Materials Dev. Div., AERE, Harwell, England), J.L.Hutchison, C.J.Wright, M.A.M.Bourke, R.I.Hill, V.S.Rainey.

J. Electrochem. Soc. (USA), vol.130, no.4, p.829-34 (April 1983).

The complementary techniques of inelastic neutron scattering and high resolution transmission electron microscopy have been used to study different aspects of the constitution of several forms of lead dioxide. The neutron scattering techniques, which are particularly sensitive to the presence of hydrogenous species, indicate that lead dioxide can accommodate widely varying amounts of hydrogen. The vibration spectra, recorded after various dehydration procedures, do not show sharp characteristic vibrations consistent with hydroxyl groups similar to those known to be present in other hydrogen-containing oxides. They suggest that the temperature-induced changes observed are consistent with the presence of adsorbed water. There appears to be a relationship between the amount of hydrogen present in a sample of PbO_2, as measured by neutron transmission, and the proportion of reduced lead present (i.e. other than Pb^{4+}) determined by chemical analysis. The electron microscopy has allowed the direct imaging of the crystal structure of β-PbO_2. This form of lead dioxide, like α-PbO_2 is prone to coherent structure intergrowth but, unlike α-PbO_2, the range of defects present does not include planar faults. (17 refs.)

71940 Structural and magnetic data on $EuSi_2$. J.Evers, G.Oehlinger, A.Weiss, F.Hulliger (Inst. fur Anorganische Chem., Univ. Munchen, Munchen, Germany).
J. Less-Common Met. (Switzerland), vol.90, no.2, p.L19-23 (April 1983). In German.
The communication deals with determinations of the structural and magnetic properties of $EuSi_2$, which at temperatures between 300 and 1150K appears to contain double-valent Eu, and to exhibit anomalous values on the crystallographic α-axis. It was decided to measure its magnetic susceptibility at higher temperatures and to determine its structural parameters by examination of a single-crystal sample in the Siemens four-circuit diffractometer. The method of preparing the sample is described. The magnetic measurements were made on a quartz-enclosed powdered sample in a Faraday balance. The results of the measurements are given; the α-axis anomaly is discussed, but without reaching a firm conclusion. (11 refs.) *C.J.O.G.*

71941 Crystal structure of the microwave dielectric resonator $Ba_2Ti_9O_{20}$. E.Tillmanns, W.Hofmeister (Inst. fur Geowissenschaften, Univ. Mainz, Mainz, Germany), W.H.Baur.
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.268-71 (April 1983).
A single-crystal X-ray study of dibarium nonatitanate, $Ba_2Ti_9O_{20}$, yielded the triclinic space group $P\bar{1}$ with $a=0.7471(1)$, $b=1.4081(2)$, $c=1.4344(2)$ nm, $\alpha=89.94(2)°$, $\beta=79.43(2)°$, $\gamma=84.45(2)°$, $V=1.476$ nm^3, $Z=4$, and $D_x=4.61$ Mg/m^3. A refinement of atomic coordinates and isotropic thermal parameters led to a residual of 0.03. The structure consists of hexagonally closest-packed layers of Ba and O atoms in the sequence $(hch)_3$. All Ti atoms reside in octahedral interstices of this closest packing. The various Ti coordination octahedra share only edges and corners with each other. One-half of the Ba atoms is twelve-coordinated by oxygen atoms, the other half is eleven-coordinated. (33 refs.)

71942 Superconducting and magnetic properties of ternary silicides in some rare earth-noble metal (Rh or Ir)-silicon systems. B.Chevalier, P.Lejay, J.Etourneau, P.Hagenmuller (Lab. de Chimie du Solide, Univ. de Bordeaux I, Talence, France).
Mater. Res. Bull. (USA), vol.18, no.3, p.315-30 (March 1983).
New families of ternary silicides have been prepared in the RE-Rh or Ir-Si systems and the crystal structures have been determined: $RERh_3Si_2$, $RE_2Rh_3Si_5$, RE_2RhSi_3 (RE=Y, La→Er), RERhSi (Y, La, Gd→Er), REIrSi (RE=La, Ce, Nd), $RERhSi_2$ and $REIrSi_2$ (RE=La→Gd). The RE_2RhSi_3 compounds crystallize with a new structural type, the other ones are isostructural with already known silicides or borides. Some of the silicides studied whose rare earths are diamagnetic (Y, La) show superconducting transitions above 1.6K. They have been compared with other superconducting ternary borides, silicides, germanides and phosphides containing rare earths and noble metals. Except the phases with Y and La which are diamagnetic or show Pauli paramagnetism, the other materials order magnetically at low temperature. The onset of magnetic transitions vs. field has been observed for some compounds below 20 kOe at 4.2K. (31 refs.)

71943 On the crystal structure of $CrWO_2$. Y.Shimony, L.Ben-Dor (Dept. of Inorganic & Analytical Chem., Hebrew Univ., Jerusalem, Israel).
Mater. Res. Bull. (USA), vol.18, no.3, p.331-5 (March 1983).
The crystal structure of $CrWO_4$ was determined on the basis of an orthorhombic symmetry with space group F222 (no.22). Unit cell dimensions are as follows: a=13.338 Å, b=12.889 Å, c=5.8308 Å. (12 refs.)

71944 New compounds in the system SrO-TiO_2-Al_2O_3 at 1300°C. A crystallographic and leaching study. H.W.Zandbergen, D.J.W.Ijdo (Gorlaeus Labs., State Univ. Leiden, Leiden, Netherlands).
Mater. Res. Bull. (USA), vol.18, no.3, p.371-4 (March 1983).
The SrO poor part of the system SrO-TiO_2-Al_2O_3 at 1300°C in air has been investigated. Two new quarternary compound structures were determined, $SrTi_3Al_8O_{19}$ and $Sr_3TiAl_{10}O_{20}$, isostructural to $Ba_3TiAl_{10}O_{20}$. The compounds TiO_2, $SrTiO_3$, $SrAl_{12}O_{19}$ and $SrTi_3Al_8O_{19}$ are stable in water at 300°C and 2 kb. All other compounds decompose under these conditions. (11 refs.)

71945 Ternary graphite intercalation compound $KCsC_{16}$: an ideal layered heterostructure. B.R.York, S.K.Hark, S.A.Solin (Dept. of Phys. & Astron., Michigan State Univ., East Lansing, MI, USA).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1470-3 (9 May 1983).
An ideal ternary heterostructure graphite intercalation compound, $KCsC_{16}$, which exhibits a stage-1 c-axis stacking sequence, ...CKCCsCKCCs..., has been prepared. The stage, stacking sequence, and $(2\times2)R0°$ in-plane structure have been confirmed by high-resolution X-ray diffraction studies which reveal a c-axis correlation range of ~350Å. The structure factor and widths of the $(00l)$ reflections calculated on the basis of the proposed stacking sequence are in excellent agreement with experimental observations. (13 refs.)

71946 X-ray diffraction investigation of cation distribution in high-temperature cubic spinels of the Mg-Mn-O system. V.P.Barkhatov, V.F.Balakirev, Yu.V.Golikov, E.G.Kostitsin (Inst. of Metall., Acad. of Sci., Sverdlovsk, USSR).
Phys. Status Solidi a (Germany), vol.76, no.1, p.57-63 (16 March 1983).
The concentrations of Mg- and Mn-ions in tetrahedral and octahedral sublattices in equilibrium cubic spinels $Mg_xMn_{3-x}O_4$ are determined by high-temperature X-ray method. The cation distribution parameter dependence versus x is found to be linear and temperature-independent in the 973 to 1263K temperature range. Two equally possible high-temperature cation configurations on the basis of obtained data for cubic equilibrium spinels are proposed: (1) $Mg^{2+}{}_{0.566x}\,Mn^{2+}{}_{1-0.566x}\cdot[Mg^{2+}{}_{0.434x}\,Mn^{3+}{}_{2-0.868x}\,Mn^{4+}{}_{0.434x}]O_4$; (2) $Mg^{2+}{}_{0.566x}\,Mn^{2+}{}_{1-0.566x}\,[Mg^{2+}{}_{0.434x}\,Mn^{2+}{}_{0.767-0.434x}\,Mn^{3+}{}_{0.466}\,Mn^{4+}{}_{0.767}]O_4$. (11 refs.)

71947 Crystal structure and characterization of $Cs_2Zn_3[Fe(CN)_6]_2.xH_2O$. P.Gravereau, E.Garnier (Lab. de Cristallochimie Minerale, Univ. de Poitiers, Poitiers, France).
Rev. Chim. Miner. (France), vol.20, no.1, p.68-77 (1983).
Powder and single crystals of $Cs_2Zn_3[Fe(CN)_6]_2.xH_2O$ have been prepared by ion exchange from the solid $Na_2Zn_3[Fe(CN)_6]_2.xH_2O$. All the lines of the X-ray powder pattern have been attributed in the rhombohedral system. Crystal structure of $Cs_2Zn_3[Fe(CN)_6]_2.6H_2O$ has been determined in the space group $R\bar{3}c$ with $a=13.140(3)$Å, $\alpha=56.81(2)°$, Z=2, V=1486.1±0.5 Å^3, $\rho_x=2.238$ Mg.m^{-3}; R=0.044 ($R_w=0.048$) for 481 unique reflections. FeC_6 octahedra and ZnN_4 tetrahedra are held together by the $(CN)^-$ ions making up a three-dimensional frame with large cavities as already found in previous $M_2{}^IZn_3[Fe(CN)_6]_2.xH_2O$ structures ($M^I=Na^+$, K^+). Cs^+ ions are randomly distributed near the centres of the 'windows' of the cavities and zeolitic water molecules are inside the cavities. (13 refs.)

71948 Discrete $Si_4Te_{10}{}^{8-}$ and $Ge_4Te_{10}{}^{8-}$ ions in $Na_8Si_4Te_{10}$ and $Na_8Ge_4Te_{10}$. B.Eisenmann, H.Schwerer, H.Schafer (Eduard-Zintl-Inst., Tech. Hochschule Darmstadt, Darmstadt, Germany).
Rev. Chim. Miner. (France), vol.20, no.1, p.78-87 (1983). In German.
The new compounds $Na_8Si_4Te_{10}$ and $Na_8Ge_4Te_{10}$ crystallize in the monoclinic system, space group $P2_1/c$ with the lattice constants s. In the structure there are discrete $Si_4Te_{10}{}^{8-}$ and $Ge_4Te_{10}{}^{8-}$ anions formed by Si_2Te_6- and Ge_2Te_6-units respectively connected by common Te-bridges. (9 refs.)

71949 Structural comparison of mixed molybdates of metals (I) and (II) related to the triclinic molybdate $ZnMoO_4$. C.Gicquel-Mayer, M.Mayer (Lab. de Chimie Minerale Structurale, Univ. de Haute-Normandie, Mont-Saint-Aignan, France).
Rev. Chim. Miner. (France), vol.20, no.1, p.88-95 (1983). In French.
The crystal structures of some mixed molybdates of metals I(Na,Ag) and II (Zn,Mg) are compared. They are grouped with the same formula $A_{2-2x}{}^{I}M_{2+x}{}^{II}(MoO_4)_3$. A comparison with $ZnMoO_4$ triclinic shows only a common motif. (5 refs.)

71950 Synthesis and characterisation of the crystalline phases of the system PbF_2-ZrF_4. C.Depierrefixe (Lab. de Chimie Minerale Structurale CNRS, Limoges, France), R.M.Awadallah, J.-P.Laval, B.Frit.
Rev. Chim. Miner. (France), vol.20, no.1, p.96-108 (1983).
By solid state reaction from 300°C up top 600°C in the PbF_2-ZrF_4 system in addition to the already known $PbZrF_6$ and Pb_3ZrF_{10} compounds, two domains of non-stoichiometry, $Pb_{1-x}Zr_xF_{2+2x}$ have been characterised. The first one, very extended ($0\leq x\leq0.18$ at 550°C) corresponds to an anion-excess fluorite-like solid solution showing a strong tendency to ordering for compositions with $x\simeq0.167$. The corresponding ordered Pb_5ZrF_{14} phase is a new example of anion-excess fluorite-related superstructure (monoclinic, pseudotetragonal, $a\simeq a_F$, $b\simeq c\simeq 3a_F$). The complex phenomena of ordering have been interpreted on the basis of a model of monodimensional clusters built up with ZrF_8 antiprisms. (13 refs.)

71951 Synthesis, structural study by X-rays and by infrared and Raman spectrometry of the basic tellurite $Li_2TeO_3.LiOH$. D.Cachau-Herreillat, A.Norbert, M.Maurin, R.Fourcade, E.Philippot (Lab. de Chimie des Materiaux, Univ. des Sci. et Tech. du Languedoc, Montpellier, France).
Rev. Chim. Miner. (France), vol.20, no.1, p.129-39 (1983).
Li_2TeO_3, LiOH was isolated by hydrothermal synthesis. This phase crystallizes in the monoclinic system, space group $P2_1/m$, Z=2, with $a=6.771(2)$, $b=6.309(2)$, $c=5433(2)$ Å and $\beta=113.20(1)°$. The structure determination and refinement was carried out with 695 independent reflections to a final R-value of 0.046. The crystal structure is built up from streets of discrete $TeO_3{}^{2-}$ anions and LiO_4 tetrahedra. A parallel study by IR and Raman vibration spectrometry was made. (17 refs.)

61.65 SPECIFIC STRUCTURE OF ORGANIC COMPOUNDS

71952 The crystal structure of dimethyl sulphoxide complex of yttrium. Lin Yong-hua, Hu Ning-hai, Zhou Qing-lian, Liu Shu-zhen, Shi En-dong, Wang Ming-yi (Changchun Inst. of Appl. Chem., Acad. Sinica, Shanghai, China).
Acta Phys. Sin. (China), vol.32, no.3, p.400-5 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
The crystal of dimethyl sulphoxide complex of yttrium $[Y(NO_3)_3.3DMSO]$ belongs to the monoclinic system, $a=13.604(4)$ Å, $b=12.669(4)$ Å, $c=11.554(2)$ Å, $\beta=100.14(4)°$ and $Z=4$. The space group is $P2_1/n$. The diffraction data were collected using PW-1100 four-circle diffractometer. The number of independent diffraction data amounts to 3615. The structure was solved by heavy-atom method. Structure parameters were refined by full matrix and block diagonal least square method to a final $R=0.080$. The result of structure analysis establishes that the polyhedral coordination of 'three-headger triprism' is formed by nine oxygen atoms surrounding the Y cation. The distances between the yttrium and the coordinating oxygens are $Y\text{-}O_{DMSO}=2.285$ Å, $Y\text{-}O_{NO(3)}{}^-=2.460$ Å. (5 refs.)

71953 Crystal and molecular structure of hexadecamethylcyclooctasiloxane, $[(CH_3)_2SiO]_8$. N.L.Paddock, S.J.Rettig, J.Trotter (Dept. of Chem., Univ. of British Columbia, Vancouver, BC, Canada).
Can. J. Chem. (Canada), vol.61, no.3, p.541-4 (March 1983).
Crystals of hexadecamethylcyclooctasiloxane are tetragonal, $a=13.9442(5)$, $c=8.5573(4)$ Å, $Z=2$, space group $P4/nnc$. The structure was solved by direct methods and was refined by full-matrix least-squares procedures to a final R of 0.034 and $R_w=0.042$ for 730 reflections with $I\geq3\sigma(I)$. The molecular structure closely resembles that of $[(CH_3)_2PN]_8$. Its comparatively rigid conformation, in which the silicon atoms form a crown, is dependent on the efficient use of van der Waals interactions between two sets of four methyl groups. Important molecular dimensions (bond lengths corrected for libration)

are: Si-O=1.629(1) and 1.635(1), Si-C=1.862(2) and 1.848(3) Å, O-Si-O=108.99(6), Si-O-Si=157.8(1) and 148.8(2)°. (35 refs.)

71954 **Intergrowths and defect structures in $Bi_9Ti_3Fe_5O_{27}$ revealed by high-resolution electron microscopy.** D.J.Smith (High Resolution Electron Microscope, Univ. of Cambridge, Cambridge, England), J.L.Hutchison.
J. Microsc. (GB), vol.129, pt.3, p.285-93 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
A high-resolution 500 kV study of the long-period (*n*-8) perovskite $Bi_9Ti_3Fe_5O_{27}$ has revealed a variety of order/disorder effects, in marked contrast to low-*n* materials, as well as the occurrence of a new two-dimensional superlattice structure corresponding to a $3\times d_{110}$ ordering along the bismuthate layers. Intergrowths of the 2-D SL phase with the 'usual' perovskite/bismuthate phase, as well as sharp interfaces between these two phases, were observed and the common occurrence of steps along these interfaces suggested ledge migration as one possible transformation mechanism. Coherent intergrowths of structural elements rather similar to tetragonal-tungsten-bronze (TTB)-type were also found and these sometimes appeared to be relics of the super-lattice phase. The chemical implications of the various observations are briefly discussed. (17 refs.)

71955 **Nonstoichiometry of inorganic solids.** W.Albers (Philips Res. Labs., Eindhoven, Netherlands).
In book: *Current topics in materials science. Vol.10*, E.Kaldis [Ed.], p.191-247. Amsterdam, Netherlands: North-Holland (1982), vi+515 pp. [0 444 86321 4]
The author discusses some thermodynamic aspects of the nonstoichiometry of inorganic solids. An introduction to the defect chemistry of pure compounds is presented. The theoretical aspects are illustrated with thermodynamic and electrical measurements on many interesting materials. (50 refs.)

71956 **Peak representing annealing of point defects and the activation energy of the process responsible for this peak.** V.I.Levit, Yu.M.Plishkin, I.E.Podchinenov (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.426-32 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
It is shown that the relationship between the activation energy of the process of annealing of point defects and the temperature at which the annealing is maximal is valid in the case of annihilation of Frenkel pairs with short internal distances, as well as in the case of correlated recombination and free migration. An allowance is made for the emission of point defects by clusters. An example is given of the use of the consequences deduced from this relationship in the interpretation of the experimental results on annealing;. (17 refs.) *A.T.*

71957 **Distribution of nitrogen atoms between interstices in the ferrite lattice at high temperatures.** L.A.Bol'shov (Polytech. Inst., Vologda, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.615-17 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An analysis is made of the previously published results of an experimental study of the solubility of nitrogen in the ferrite phase of high-chromium steels (16.8-31.6 wt.% Cr) at temperatures 1250-1350°C. The results suggest that at about 1300°C the nitrogen atoms occupy preferentially the tetrahedral interstices in the ferrite. (9 refs.) *A.T.*

71958 **Temperature dependence of accumulation efficiency and annihilation kinetics of primary Frenkel defects in KCl and KCl-I crystals in the temperature range 15-80K.** V.V.Gavrilov, S.N.Nesterova, A.M.Sitdikov, S.A.Chernov, S.S.Etsin.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.35-42 (1983). In Russian.
Optical absorption relaxation induced by a pulse accelerator (10 ns, 250 keV, 10^2 A/cm^2) in KCl and KCl-I in the temperature range 15-80K has been studied. It is shown that when I^- is introduced in the KCl crystal the *F-H*-pair distribution shift takes places in the direction of the average distance increase in the pair. This leads to the *F-H*-pair stability increase in KCl-I as compared to pure KCl. (19 refs.)

71959 **Simulation of point defect accumulation kinetics in one-dimensional crystal.** Yu.Kh.Kalnin, Yu.Yu.Krikis.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.104-6 (1983). In Russian.
Simulation of point defect accumulation kinetics is carried out in a one-dimensional crystal. Defects pair correlations are taken into account. The obtained results are in good agreement with the theoretical model proposed previously. (5 refs.)

71960 **In-situ TEM observations of loop punching from helium platelet cavities in molybdenum.** J.H.Evans (Metall. Div., AERE, Harwell, England), A.van Veen, L.M.Caspers.
Scr. Metall. (USA), vol.17, no.4, p.549-53 (April 1983).
In an extension of earlier HDS/TEM work (see ibid., vol.15, p.323, 1981) on the nucleation and growth of helium clusters in molybdenum, the authors have demonstrated as expected that TEM specimens with (011) surfaces can successfully limit the loss of ⟨111⟩ loops to the free surface. In particular the property that two of the ⟨111⟩ glide directions lie parallel to the foil surfaces has indicated clearly that the electron beam can induce the in-situ punching of ⟨111⟩ interstitial loops from some of the helium platelets. Direct electron beam heating of the specimen was eliminated as a mechanism but two other possibilities were suggested, one based on the excitation of helium atoms to increase the internal cavity pressure, the second based on direct electron-molybdenum atom energy transfers to overcome an activation barrier for loop nucleation. Both fit the observations in the sense that the TEM beam density (electrons/unit area) seemed to be the controlling parameter. The TEM electrons also were able to initiate the glide of interstitial loops evidently pinned by helium atoms at the loop periphery. (13 refs.)

71961 **Reduction of dislocations in LPE layers due to the action of thermal stresses.** Tu Xiang-zhong (Inst. of Semiconductors, Acad. Sinica, Beijing, China).
Acta Phys. Sin. (China), vol.32, no.3, p.315-24 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
The author presents a model of the reduction of dislocations in LPE layers by the formation of ⟨110⟩ oriented interfacial dislocations parallel to the surface of the substrate due to the glide motion of substrate threading dislocations which is driven by the thermal stress produced by a temperature difference. In the temperature gradient LPE under a steady natural convection flow, there is a temperature difference across the thickness of the substrate. The temperature difference can cause a thermal shear stress in the fixed substrate. Thick GaAs and $Ga_{1-x}Al_xAs$ (x<0.3) layers were grown on (100) GaAs substrates. The estimated value of the thermal stress is slightly greater than the critical resolved shear stress for the formation of ⟨110⟩ oriented dark line defects. The observation of surface etch pits shows that the epitaxial layers have lower dislocation densities than that of the substrates or are even dislocation-free. (24 refs.)

71962 **A modified stress distribution for a subsonic moving dislocation.** K.Murayama, R.L.Thom, M.R.Lin, L.M.Angers, R.S.Herrick, S.H.Hong, D.E.Luzzi, Y.K.Park, D.R.Williams, M.S.Zedalis, J.Weertman (Dept. of Materials Sci. & Engng., Northwestern Univ., Evanston, IL, USA).
Mech. Mater. (Netherlands), vol.2, no.1, p.61-6 (April 1983).
In earlier moving edge dislocation theory the stresses across a slip plane are not continuous. A modification is proposed which corrects for this defect using smeared out dislocation theory at subsonic speed. Near the Rayleigh velocity, the smeared out subsonic dislocation theory is no longer applicable. The proposed modification may be extended for use in theory on earthquake faults. (2 refs.)

71963 **Semiconductor device technology and dislocation theory.** K.Sumino (Tokoku Univ., Sendai, Japan).
Oyo Buturi (Japan), vol.51, no.11, p.1246-54 (Nov. 1982). In Japanese. [received: March 1983]
The dislocation phenomena which occur in semiconductor elements including slip, and warp are described. In semiconductor crystal deformation the calculated and measured temperatures curves (800-950°C) for FZ silicon in a plot of shear v. warping are plotted. The relationship of dislocations with doping for FZ and CZ silicon is reviewed. (21 refs.) *M.O.*

71964 Dislocation motion in cellular structures. Y.Pomeau, S.Zaleski (Groupe de Phys. du Solide, Ecole Normale Superieure, Paris, France), P.Manneville.
Phys. Rev. A (USA), vol.27, no.5, p.2710-26 (May 1983).
The slow motions of cellular structures of parallel rolls are described by the amplitude equation in the weakly nonlinear domain. As this equation has a variational structure, the Peach-Kohler force exerted on a dislocation can be computed in the same way as for usual crystals. When the cellular structure is really described by variational equations, this force keeps its variational origin (it is the gradient of some energy) and vanishes for some optimal wave number. In thermoconvection in porous layers, this variational structure of the dynamics is lost at perturbative order beyond the one giving the usual amplitude equation. Therefore, the notion of an optimal wave number loses its meaning, and the quantity equivalent to the Peach-Kohler force does not vanish anymore at the wave number of marginal stability for perpendicular diffusion, contrary to what happens in variational systems where this condition defines the optimal structure. Another consequence of this nonvariational dynamics is the occurrence of gliding motion of dislocations in uniformly curved rolls, a situation where no Peach-Kohler force exists in variational systems. (14 refs.)

71965 Are the core structures of dislocations and grain boundaries resolvable by HREM?. A.Bourret, J.Thibault-Desseaux, C.D'Anterroches, J.M.Penisson, A.De Crecy (Dept. de Recherche Fondamentale, CENG, Grenoble, France).
J. Microsc. (GB), vol.129, pt.3, p.337-45 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
Linear or planar defect structures have been recently studied by high resolution electron microscopy (HREM). Defects are generally difficult to solve for several reasons: they are non-periodic and their images are limited to a very few projections along low index axes. For edge dislocations in materials having a high lattice friction, image analysis is possible and relatively fine details are now available about core radii and location of the atom pairs. The accuracy, however, of the proposed structures is within ±0.025 nm if a priori information is known. This is not always sufficient to distinguish between several models. For a high angle tilt grain boundary the situation is comparable. A discussion of the errors introduced by several factors (object orientation, optical axis alignment) and measurement of experimental parameters is presented. At present all the information content of an image is not used: intensity profiles and quantitative comparison of simulated and experimental images should provide better ways for solving an unknown structure. However, the improvement of the point resolution is the key factor for further progress in defect analysis. (17 refs.)

71966 Dislocation nucleation and precipitation of impurity in calcium-doped NaCl-KCl crystals. S.R.Ghadekar, B.T.Deshmukh (Dept. of Phys., Nagpur Univ., Nagpur, India).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.321-5 (9 May 1983).
In calcium-doped mixed NaCl-KCl crystals, Ca^{2+} ion sites were selectively sensed by a suitable etchant. Different impurity substructures, viz. arrays, close-networks, unevenly distributed clusters, were formed by the dopant ions in the lattice. Non-uniform distributions of the impurity ions in the lattice does not nucleate dislocations. Non-structural impurities like precipitates were found to take different forms, viz. elongated rods, rectangular forms, with different orientations. Dislocations showed strong preference for the nucleation of the precipitates. The nucleation of the precipitates at sites other than those of dislocations is discussed. (28 refs.)

71967 Structural changes in nickel after ultrasonic action with subthreshold amplitudes in liquid helium. V.K.Aksenov, O.I.Volchok (Physicotech. Inst., Acad. of Sci., Khar'kov, Ukrainian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1769-70 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3125-8 (Oct. 1982). [received: April 1983]
The authors present data from investigations on the dislocation structure and the yield point $\sigma_{0.2}$ of nickel after acoustic irradiation in liquid helium, in liquid nitrogen, and at room temperature. Measurements are made using electron microscopy. (12 refs.)

71968 Theoretical latent hardening of crystals in double-slip. II. FCC crystals slipping on distinct planes. K.S.Havner (Dept. of Civil Engng., North Carolina State Univ., Raleigh, NC, USA), S.A.Salpekar.
J. Mech. & Phys. Solids (GB), vol.31, no.3, p.231-50 (1983).
For pt.I see ibid., vol.30, p.379 (1982). The line of investigation of theoretical latent hardening in axially-loaded cubic crystals initiated by K.S. Havner and A.H. Shalaby (1977), based upon their 'simple theory' of rotation-dependent crystal anisotropy (and continued through various other works), is completed with the analysis of finite double-slip on distinct planes in FCC crystal lattices. In conjunction with a previous study by the present authors of double-slip on a common plane (Havner and Salpekar, 1982), the general theoretical result is that any FCC crystal which initially deforms homogeneously from the virgin state in double-slip, under either tensile or compressive axial loading, will continue in that mode of deformation to very large shears ($\gamma=1.5$ and beyond). A comparative review of various hardening rules (including the 'simple theory') with regard to both theoretical predictions and mathematical issues is included and may be found instructive. 61.70N Grain and twin boundaries

71969 Effects of rigid grain separation on the diffusive growth of crack-like cavities on grain boundaries. T.-L.Sham (Div. of Engng., Brown Univ., Providence, RI, USA).
Mech. Mater. (Netherlands), vol.2, no.1, p.9-18 (April 1983).
Previous analyses of diffusive growth of grain boundary cavities in the limiting case of a crack-like mode under the rigid grain assumption have assumed that the effect of grains separation rate on the cavity growth rate is negligible. This is more valid when the cavity growth rates are very high. Here, the author investigates the validity of this assumption at lower cavity growth rates by incorporating the contribution of the rigid grains separation rate in the analysis. The resulting geometry of the crack-like cavity near its tip is given. This information is used to set boundary conditions for the rigid grain model. Numerical results for the applied stress versus the cavity growth rate are presented. They are compared with those given by Chuang, Kagawa, Rice and Sills (1979), whose analysis assumes the rate of separation of the grains to be small compared to the cavity growth rate. Comparison with the results of Chuang et al. (1979) for the rupture time based on cavity growth to coalescence is also made. (9 refs.)

71970 Evidence for the isomorphism of the low-temperature form of hexaamminecobalt(III) iodide with the room-temperature structure of hexaamminecobalt(III) chloride. T.R.Welberry, B.E.Williamson (Res. School of Chem., Australian Nat. Univ., Canberra, Australia).
Acta Crystallogr. Sect. C (Denmark), vol.C39, pt.5, p.513-14 (15 May 1983).
Crystals of $[Co(NH_3)_6]I_3$ which are cubic at room temperature become polydomained on cooling below 280K. The authors show that oscillation photographs taken below the transition may be indexed on the assumption that 12 twinned orientations of a monoclinic cell are present in the crystal. With the adoption of this new cell, the powder data of Borzecka et al. [Acta Phys. Pol.A (1980)] have been reinterpreted to yield: $a=13.44$ (2), $b=23.02$ (3), $c=13.37$ (2) Å, $\beta=110.69$ (7)°. (22 refs.)

71971 Structure and properties of chromomanganese austenitic steels hardened by hydraulic extrusion. G.A.Pegushina, V.A.Teplov (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.538-42 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the structure of 60G12Kh9F2 steel after hardening by hydraulic extrusion and rolling. When the degree of deformation was high, characteristic noncoherent twin bands formed in the extruded material. The orientations of the crystal lattices in these twins differed from that expected. (9 refs.) *A.T.*

71972 Investigation of changes in the grain-boundary structure as a result of recrystallization of a magnesium alloy after weak deformation. R.Z.Valiev, V.Yu.Gertsman, O.A.Kaibyshev (Ordzhonikidze Aviation Inst., Ufa, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.554-8 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A correlation was established between the behaviour of defects formed in grain boundaries as a result of capture of lattice dislocations in the course of plastic deformation and the changes in the microstructure of weakly deformed samples of alloy MA8 during annealing. The deformation defects, which

determined the grain-boundary structure, also played an important role in the process of recrystallization after weak deformation. (17 refs.) *A.T.*

71973 Crystallogeometric features of the subgrain structure and their relationship to the deformation texture. A.N.Vergazov, V.V.Rybin, Yu.F.Titovets.
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.559-70 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Experimental studies were made of the distributions of orientations and relative misorientations of subgrains in molybdenum. The results were analyzed from the point of view of the mechanism of formation of the subgrain structure and the origin of deformation textures. (13 refs.) *A.T.*

71974 High resolution and conventional electron microscopy studies of repeated wedge microtwins in monoclinic rare earth sesquioxides. C.Boulesteix (Lab. de Microscopie Electronique Appliquee, Marseille, France), B.Yangui, G.Nihoul, A.Bourret.
J. Microsc. (GB), vol.129, pt.3, p.315-26 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
High resolution and conventional studies have been made on the inclined twin boundaries occurring near the tip of wedge microtwins in the case of repeated wedge microtwins occurring at twin intersections. These inclined boundaries appear to be continuous and all the atomic planes are also continuous so that it is suggested that the use of the term 'inclined coherent boundaries' instead of 'incoherent' which one generally employs, in analogy to the case of precipitates in a matrix. This is different from what occurs in the case of isolated wedge microtwins for the same material and for the same kind of twins where the inclined twin boundary is really not coherent, being made of non-inclined coherent regions separated by steps containing a dislocation. A comparative study of the different roles related to the different structures of inclined twin boundaries for isolated and repeated wedge microtwins has been made, and also a comparative study of the mechanism of stress relaxation to each case. The studies have been made on (313) twins of a monoclinic samarium sesquioxide. (17 refs.)

71975 Determination of grain boundary rotation parameters from Kikuchi patterns. II. Experimental optimization of the analysis of grain boundary orientation relationships and verification of the accuracy of the proposed method. H.O.Martikainen (Dept. of Mining & Metall., Helsinki Univ. of Technol., Espoo, Finland), V.K.Lindroos.
Phys. Status Solidi a (Germany), vol.76, no.2, p.709-19 (16 April 1983).
For pt.I see ibid., vol.75, p.559 (1983). The use of an advanced electron optical method for the experimental determination of grain boundary orientation relationships is demonstrated in connection with the study of structural BCC steel after large degree of high temperature deformation. Furthermore, the accuracy of the analytical method proposed in Part I is experimentally verified using two different approaches based on (1) the tilting of the foil and on (2) the multiplication test using rotation matrices of three grain boundaries of a triple junction. (10 refs.)

71976 On calculated energies of segregation, grain boundary energies and lattice energy functions. J.T.Wetzel, E.S.Machlin (Henry Krumb School of Mines, Columbia Univ., New York, NY, USA).
Scr. Metall. (USA), vol.17, no.4, p.555-8 (April 1983).
Values of the energy of segregation provided by computer simulation of grain boundary segregation are higher than those obtained using published values of the solute enhancement factor at grain boundaries. It is suggested that the discrepancy is caused by the lattice energy functions used for the calculations. A new lattice energy function gives better agreement between calculated and observed results when applied to (210)/[001] tilt grain boundaries of the metals Au, Cu, Ni and Pb. (10 refs.)

71977 Dislocation behavior in the vicinity of grain boundaries in FCC metals and alloys. H.Fujita (Dept. of Materials Sci. & Engng., Osaka Univ., Osaka, Japan), K.Toyoda, T.Mori, T.Tabata, T.Ono, T.Takeda.
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.195-204 (April 1983).
Dislocation behavior in the vicinity of grain boundaries has been investigated by in situ deformation with a 3 MeV electron microscope in bicrystals of aluminum, copper and copper-aluminum alloys. The dislocations in a Cu-5 wt.% Al alloy can move through the boundary with misfit angle 5° at some parts where the dislocations pile up two-dimensionally when the tensile axis is perpendicular to the tilt boundary. When the stacking fault energy and the misfit angle of boundary increase, the dislocations become hardly possible to move through the boundary. Three-dimensional pile-up of the dislocations heavily occurs against the boundary in a crystal, whose Schmid factor is larger than the other, when the tensile axis is perpendicular to the boundary. The dislocation tangles, however, are formed in another crystal. Many slip systems are operated in the vicinity of the boundary and the dislocation tangles are easily formed in both crystals when the tensile axis is parallel to the boundary. Recrystallization easily occurs in regions near the boundary when the specimens are stretched along the boundary. (20 refs.)

71978 Landau theory of periodic antiphase boundaries in CuAu alloys. W.L.McMillan (Dept. of Phys., Univ. of Illinois, Urbana, IL, USA).
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.111-14
A Landau theory is developed to discuss properties of periodic antiphase boundaries in CuAu alloys. The properties of the modulated phase are calculated. (6 refs.)

71979 Shear band interactions with crystals in partially crystallised metallic glasses. P.E.Donovan, W.M.Stobbs (Dept. of Metall. & Materials Sci., Univ. of Cambridge, Cambridge, England).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.61-76 (April 1983).
The morphology of shear bands in two partially crystallised metallic glasses, $Ni_{80}B_{20}$ and $Cu_{50}Zr_{50}$, is deduced by transmission and scanning electron microscopy. A number of different types of crystal/shear band interaction have been characterised, providing evidence both for the dilatational model of shear band deformation and for long range interactions between an operating shear band and a stress raiser in the amorphous matrix. Qualitative differences in the mechanical properties of the two partially crystallised glasses examined are rationalised in terms of the interactions observed. (22 refs.)

71980 An investigation of order/disorder in a chromia-doped rutile by high-resolution electron microscopy. G.J.Wood (High Resolution Electron Microscope, Univ. of Cambridge, Cambridge, England), L.A.Bursill, D.J.Smith.
J. Microsc. (GB), vol.129, pt.3, p.263-73 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
Computer image simulations predict that the detailed atomic arrangements along extended CS defects in slightly-reduced rutile may be identified in 500 kV high-resolution electron micrographs. Experimental images from a chromia-doped rutile have generally confirmed these predictions although also indicating that considerable disorder remains. The need for very careful control of sample preparation, including heat treatments, is emphasized. (21 refs.)

71981 The high resolution electron microscopy of stacking defects in Cu-Zn-Al shape memory alloy. J.M.Cook (Dept. of Metall. & Materials Sci., Univ. of Cambridge, Cambridge, England), M.A.O'Keefe, D.J.Smith, W.M.Stobbs.
J. Microsc. (GB), vol.129, pt.3, p.295-306 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
The characteristic defects in the martensitic phase of the memory alloy Cu-Zn-Al have been investigated using the Cambridge University 600 kV High Resolution Electron Microscope. Conditions are found under which the images can be quantitatively simulated when this involves the transfer of structural information at resolutions beyond the first zero of the contrast transfer function. Defects of sequence-type were positively identified by the comparison of high-resolution micrographs with full dynamical image simulations. (12 refs.)

71982 Microstructure of Sm_5Ni_{19} intermetallic compound observed by high-resolution electron microscope. S.Takeda, H.Horikoshi, Y.Komura (Dept. of Materials Sci., Hiroshima Univ., Hiroshima, Japan).
J. Microsc. (GB), vol.129, pt.3, p.347-58 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
The method of high-resolution electron microscopy is applied to study the microstructure of the Sm-Ni intermetallic compound whose composition is near Sm_5Ni_{19}. Several new polytypic structures (5 T, 7 T, 15 R and 18 R) are found and their crystal structures are analysed by high-resolution imaging combined with electron diffraction. Various kinds of defects are observed and the atomic arrangements near the defects are deduced; the defects include stacking faults in Sm_5Ni_{19}, complicated defect structure which changes the stacking sequence of Sm_5Ni_{19}, and lattice defects in the region of terminating the intergrowth. 71983 Direct evidence for the site of substitutional carbon in GaAs using localised vibrational mode spectroscopy. W.M.Theis (Univ. Res. Center, Wright State Univ., Dayton, OH, USA), K.K.Bajaj, C.W.Litton, W.G.Spitzer.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.166-18 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
High resolution transmission measurements using Fourier transform infrared spectroscopy of the localized vibrational mode (LVM) due to substitutional carbon in GaAs provide direct evidence that the carbon resides predominantly on the As sublattice (C_{As}). These spectra are found to be the near superposition of at least four bands which may be fit to a combination of Lorentzian functions. The LVM produced by Si_{As} and GaAs exhibits similar structure which also may be fitted by Lorentzians. The only satisfactory explanation is that these spectral features arise from shifts due to different nearest neighbor configurations of the two GaAs isotopes. There is no experimental indication of C_{Ga}. In addition, the full widths at half maximum of these bands are much smaller than previously believed. (13 refs.)

71984 Tendency to nearly cubic local lattice structure around interstitial hydrogen in the alkali metals. G.Solt (Inst. de Phys., Neuchatel Univ., Neuchatel, Switzerland), M.Manninen, H.Beck.
Solid State Commun. (USA), vol.46, no.4, p.295-8 (April 1983).
The behaviour of the lattice response in the BCC alkali metals and the change in sign of the impurity-host interaction between first and second neighbour distances are shown to cooperate to build up a relaxed atomic environment which, for the D_{4h} 'octahedral' interstitial position, is close to a

regular octahedral coordination. The calculation is done by using the self-consistent electron density for a proton in jellium to take into account non-linear screening, and the relaxed crystal structure is found by the method of lattice statics. The displacements around the hydrogen impurity are found to be many time larger than those predicted earlier by use of the spherical solid model. (14 refs.)

71985 Suppressing Al outdiffusion in implantation amorphized and recrystallized silicon on sapphire films. R.E.Reedy (Naval Ocean Systems Center, San Diego, CA, USA), T.W.Sigmon, L.A.Christel.
Appl. Phys. Lett. (USA), vol.42, no.8, p.707-9 (15 April 1983).
In this work the authors have used a dual implant and anneal process to significantly improve the crystalline quality of 0.3-μm silicon on sapphire films while simultaneously minimizing the outdiffusion of free Al from the sapphire into the Si layer. The crystalline quality, as measured by MeV ^{4}He$^+$ ion channeling closely approached $\langle 100\rangle$ bulk Si values and the Al concentration, as measured by secondary ion mass spectrometry, was less than 3×10^{15} cm^{-3}. An explanation for why similar techniques result in large amounts of aluminum outdiffusion when applied to 0.5-μ films is proposed. (7 refs.)

71986 Effect of argon implantation on the activation of boron implanted in silicon. A.Milgram, M.Delfino (Fairchild Advanced Res. & Dev. Lab., Palo Alto, CA, USA).
Appl. Phys. Lett. (USA), vol.42, no.10, p.878-80 (15 May 1983).
Argon ions were implanted either prior or subsequent to an ion implantation of boron into silicon wafers. After isochronal annealing at temperatures ranging from 500 to 900°C, the samples were examined by a spreading resistance-carrier concentration profile and secondary ion mass spectroscopy. It is shown that argon implantation at a dose sufficient to produce an amorphous layer inhibits the electrical activation and diffusion of boron implanted in silicon. (12 refs.)

71987 Specific site location of S and Si in ion-implanted GaAs. R.S.Bhattacharya, P.P.Pronko (Universal Energy Systems Inc., Dayton, OH, USA), S.C.Ling.
Appl. Phys. Lett. (USA), vol.42, no.10, p.880-2 (15 May 1983).
Rutherford backscattering and proton induced X-ray emission in combination with channeling have been used to investigate the specific site location of S and Si implanted in GaAs through the asymmetry in their channeling dips. A pronounced asymmetry is observed for $\langle 110\rangle$ scans parallel to the $\{110\}$ plane in the case of S, whereas no such asymmetry is found for the case of Si. These results clearly indicate that S predominantly occupies one sublattice site which is shown to be the As site whereas Si occupies both Ga and As sites in about equal concentrations. (11 refs.)

71988 Calculation of ion project range on amorphous targets of ternary and quarternary alloys. Wang De-ning, Guo Hu-ling, Wnag Wei-yuan (Shanghai Inst. of Metall., Acad. Sinica, Shanghai, China).
Acta Phys. Sin: (China), vol.32, no.3, p.393-9 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
The authors have calculated the project range for ions on amorphous targets made of ternary or quarternary alloys. Their calculations are based upon Vagard's law, which establishes that the project range in multi-component system can be obtained by linear combination of those of its composing binary alloy compounds. The calculated project ranges of systems H$^+\rightarrow$GaAlAs, InAs and InGaAs, Be$^+\rightarrow$GaInSb and InAsSb, and B$^+\rightarrow$Hg$_{0.8}$Cd$_{0.2}$Te, agree well with the experimental or calculated results published in literatures. The dependences of project range on implantation energy and composition in the processes H$^+\rightarrow$GaInAsP and GaAlAsSb, and ions$\rightarrow$PbSnTe are also calculated. (12 refs.)

71989 High-dosage implantation of oxygen into surface layers of Si and SiO$_2$. G.F.Romanova, P.I.Didenko, R.I.Marchenko.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.23-8 (1982). In Russian.
The profiles of high-dosage oxygen implantation into silicon and layers of silicon dioxide are studied by secondary ion mass spectrometry. The formation of SiO$_2$ during the implantation of ^{16}O$^+$ into Si is found to start from a dosage of 10^{17} ion. cm^{-2}, initially in the form not of a continuous layer but of individual impregnations of SiO$_2$ in amorphised Si. At doses of 10^{18} ion. cm^{-2} a continuous layer of SiO$_2$ with a clearly marked Si-SiO$_2$ boundary emerges on the silicon surface. Implantation of ^{16}O$^+$ into thermal SiO$_2$ causes changes in the structure of the oxide. Mechanisms for the interaction of ^{16}O$^+$ with Si and in SiO$_2$ are discussed. (15 refs.) *L.M.H.*

71990 Limiting doses for ion doping of metals. N.V.Makarets, G.L.Fal'ko, A.M.Fedorchenko (T.G. Shevchenko State Univ., Kiev, Ukrainian SSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.421-5 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A theoretical study is made of the accumulation of impurities resulting from high-fluence high-temperature ion implantation of impurities in metals subject to an allowance for the sputtering of the target surface. The limiting dose of the remaining impurity is found and its dependence on the ion energy and temperature are determined. For energies of the order of tens of kiloelectron-volts the limiting dose is very small. This dose can be increased considerably by increasing the target temperature. (5 refs.) *A.T.*

71991 Helium reemission during implantation of silicon carbide. S.Miyagawa, Y.Ato, Y.Miyagawa (Government Industrial Res. Inst., Nagoya, Japan).
J. Appl. Phys. (USA), vol.54, no.5, p.2302-6 (May 1983).
Reemission has been measured during implantation of 1 keV and 20 keV helium ions in CVD SiC at room temperature and at 600°C. The reemission behavior depends strongly on target temperature as well as ion energy, and there exists a close relationship between the reemission behavior and surface features. The flaking of CVD SiC is explained by crack propagation through the implanted layer, with gas pressure being the driving force for cracking. The effects on the reemission behavior of prebombardment with helium ions having continuous energy distribution distribution have been also measured. (16 refs.)

71992 Argon implantation in GaAs: damage and lattice site location analyses. A.K.Rai, R.S.Bhattacharya, P.P.Pronko (Universal Energy Systems Inc., Dayton, OH, USA), S.C.Ling.
J. Appl. Phys. (USA), vol.54, no.5, p.2307-11 (May 1983).
The recrystallization behavior of Ar$^+$implanted GaAs has been studied using transmission electron microscopy and Rutherford backscattering channeling and proton induced X-ray emission techniques. Ar$^+$ implanted in undoped GaAs at 700 keV to a fluence of 5×10^{15} cm^{-2} has been used in the present investigation. Formation of microtwins are observed after annealing at 400°C. These microtwins start to anneal at about 600°C and disappear completely at about 850°C at which point Ar bubbles are observed to form along with dislocations. Lattice location experiments show that the Ar atoms are randomly distributed in the lattice. (12 refs.)

71993 The nature of defect layer formation for arsenic ion implantation. S.Prussin, D.I.Margolese, R.N.Tauber (TRW Electronics Systems Group, Redondo Beach, CA, USA).
J. Appl. Phys. (USA), vol.54, no.5, p.2316-26 (May 1983).
A series of $\{100\}$ silicon wafers were implanted with As ions over the range of 1×10^{13} at. cm^{-2} to 1×10^{16} at. cm^{-2} with energies of 50, 100, and 190 keV, using a commercial ion implanter, the Varian 200-DF4. Two end stations were used, the Waycool which provided good contact between the wafers and a thermal sink and the Wayflow, which holds the wafers without any provision for obtaining such contact. Precise values of amorphous layer depth were obtained by a newly developed technique, using direct measurement of the depth exposed by a tapered groove. For the Waycool implanted wafers, the amorphous layer depth increased with dose. For the Wayflow wafers, the amorphous layer depth increased to a maximum and then decreased, finally disappearing at the higher doses. Combining shallow angle-lapping, etching, and profilometry, it was possible to study the submerged amorphous layers originating at the threshold dose for the 190-keV implantations. For Waycool implanted wafers, the surface crystalline layer thickness decreased and disappeared with increased dose. For Wayflow wafers, the surface crystalline layer increased with dose, meeting the crystalline substrate which grew from the opposite direction. The differences in defect structure between Waycool and Wayflow implanted wafers are attributed to the dynamic annealing which occurs during implantatiuon. The defects remaining after a low temperature transformation anneal are correlated to dynamic annealing effects. (28 refs.)

71994 Si implantation in GaAs. R.S.Bhattacharya, A.K.Rai, Y.K.Yeo, P.P.Pronko (Universal Energy Systems Inc., Dayton, OH, USA), S.C.Ling, S.R.Wilson, Y.S.Park.
J. Appl. Phys. (USA), vol.54, no.5, p.2329-37 (May 1983).
High-resolution Rutherford backscattering, transmission electron microscopy, and proton-induced X-ray emission with channeling have been used to investigate the damage and lattice site location of Si-implanted GaAs. Semi-insulating Cr-doped GaAs(100) crystals were implanted at room temperature with Si$^+$ ions of single (120 keV) and multiple energies (50-400 keV). The total dose of implanted ions varies from 3×10^{15} cm^{-2} to 5×10^{15} cm^{-2}. The residual damage and the lattice location of the implant are determined after 15 min annealing of the samples at 850°C and 950°C in addition to the usual dislocation loops. However, after annealing at 950°C, the primary residual damage consists of dislocation loops in addition to some small precipitates. Electrical activation efficiency has been measured in the case of 3×10^{15} cm^{-2} implant and found to be very low ($\leq$2%). Si$_{Ga}$-Si$_{As}$ neutral pair association is suggested to be the most probable reason for low electrical activity. (7 refs.)

71995 Transmission electron microscopic observation of precipitates in Si$^+$ ion-implanted GaAs. G.Das (Systems Res. Labs. Inc., Dayton, OH, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.969-70 (April 1983).
Radiation damage in the form of dislocation loops and an amorphous layer was observed in Si$^+$ ion-implanted GaAs by transmission electron microscopy (TEM) and reflection electron diffraction. Precipitates in heavily Si$^+$ ion-implanted GaAs were observed at room temperature. These precipitates are matched with those of SiAs$_2$. (3 refs.)

71996 Ion-implantation associated defect production in silicon. J.R.Troxell (Electronics Dept., General Motors Tech. Center, Warren, MI, USA).
Solid-State Electron. (GB), vol.26, no.6, p.539-48 (June 1983).
Defects produced during ion implantation have traditionally been removed during high temperature ($\geq$1200K) thermal processing. The current industry trend towards lower temperature processing will require new techniques for suppressing defect formation associated with ion implantation. This paper details the characterization and identification of the electrically active defects which are produced during low dose ion implantation. Several of the observed defect levels can be correlated with defects which have been identified in electron irradiated silicon. However, a defect level near mid gap, $H(0.53)$, which should be the dominant recombination center in p-type samples, cannot be correlated with previously identified defects. Similarly, the $H(0.20)$ level is found to anneal near 420K, and thus does not correlate well with the known properties of the divacancy, which introduces a similar trapping level. (58 refs.)

71997 Ion implantation process modelling. G.Drozdy, T.Lohner, P.Revesz, K.Tarnay, J.Gyulai (Central Res. Inst. for Phys., Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.125-8 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
A simulation program for implantation (IMPLAN) has been developed as part of a complete silicon planar technology simulation program (STEP, Silicon Technology Evaluation Program). The input parameters of IMPLAN are the type of implanted ions, the target material, the kind of the eventual covering surface layer and its thickness, the energy of the ion implantation and the dose. The output is the dopant profile in numerical or graphical format. Joined half-Gaussian and Pearson distributions are used in the program in order to get high accuracy. To measure implanted depth profiles, the authors used a high resolution Rutherford backscattering (RBS) technique. Comparison of the experimental results and simulations shows that the difference between theory and experiment is mostly less than the errors of the measurements. (8 refs.)

71998 Gettering of oxygen in Si wafers damaged by ion implantation and mechanical abrasion. J.C.Mikkelsen,Jr. (Xerox Palo Alto Res. Centers, Palo Alto, CA, USA).
Appl. Phys. Lett. (USA), vol.42, no.8, p.695-7 (15 April 1983).
Isotopic substitution of ^{18}O was used in conjunction with secondary ion mass spectrometry to distinguish the source of gettered oxygen associated with damage produced in Si wafers by As ion implantation and by mechanical abrasion. It was found that oxygen was gettered from annealing ambients, exhibiting an enhanced diffusivity in the vicinity of the damaged layers at 600°C. On the contrary, the oxygen originally dissolved in the wafers was unaffected by the damage, not being gettered by either type of damage and having the same diffusivity as that in undamaged Si crystals. These results are compared with published reports of ^{16}O analysis of similar experiments. (16 refs.)

71999 PL/1 program computes dopant concentration. J.Setian.
Electronics (USA), vol.56, no.7, p.167-9 (7 April 1983).
Presents a PL/1 program which computes the dopant concentration in a silicon wafer for both the predeposition and drive-in steps. The first step computes predeposition values and gives the precise amount of impurity that should be introduced into the crystal lattice of the wafer. Then the drive-in operation provides the final junction depth and impurity profile. (1 ref.)

72000 A correlation of atomic and electrical measurements of Cr and residual donors in thermally processed semi-insulating GaAs. P.K.Vasudev, R.G.Wilson (Hughes Res. Labs., Malibu, CA, USA), C.A.Evans,Jr., V.R.Deline.
Solid-State Electron. (GB), vol.26, no.6, p.565-7 (June 1983).
Chromium redistribution resulting in residual donor decompensation has been proposed to explain near-surface type-conversion in furnace-annealed, semi-insulating GaAs. The authors report correlations of Cr depth profiles and residual donor atom densities determined by SIMS with Hall effect and C-V electrical measurements of carrier densities which substantiate the above hypothesis. Furthermore, a 1:1 Cr-to-donor compensation ratio is observed for Cr doping levels of $\sim 10^{17}$ cm^{-3}. (9 refs.)

61.70Y Interaction between different crystal structure defects

72002 The interaction between point defects introduced by implantation and dislocations in silicon. V.V.Kalinin, N.N.Gerasimenko (Inst. of Semiconductor Phys., Acad. of Sci., Novosibirsk, USSR).
Phys. Status Solidi a (Germany), vol.76, no.1, p.65-70 (16 March 1983).
Defects appearing after boron and phosphorus ion implantation and annealing at 760°C in Si specimens having no 'primary' imperfections and having misfit dislocation networks as well as dislocation loops, are studied. Perfect specimens form characteristic rod-like defects (RDs). In specimens having 'primary' dislocations generated by a prior boron ion implantation and high-temperature annealing the number and sizes of RDs is considerably lower. If primary dislocations were generated by a prior phosphorus ion implantation, then, instead of RDs, a great number of dislocation loops of interstitial type are formed in their vicinity. Possible causes of the influence of the dislocation type upon the nature of the dislocation-point defect interaction are discussed. (16 refs.)

72003 Interaction of radiation defects with iron impurities in GaAs crystals. V.V.Teslenko, E.Yu.Brailovskii, I.D.Konozenko, N.Kh.Pambukhchyan (Inst. of Semiconductors, Acad. of Sci., Kiev, Ukrainian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1422-3 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2199-201 (Dec. 1982). [received: May 1983]
The authors have determined the ESR spectra of GaAs:Fe in order to study the processes of the interaction between radiation defects and iron atoms during electron irradiation and in the course of subsequent annealing. (8 refs.)

61.80B Laser beams

72005 Direct measurement of the melt depth of silicon during laser irradiation. Y.Hayafuji, Y.Aoki, S.Usui (SONY Corp. Res. Center, Yokohama, Japan).
Appl. Phys. Lett. (USA), vol.42, no.8, p.720-2 (15 April 1983).
The authors have studied the change in morphology of laser irradiated silicon wafers by annihilating the oxygen thermal donors and the oxidation-induced stacking faults in order to verify the melting of the near-surface regions. The laser beam used was of 1.06 μm with a diameter of 40 μm, generated from a *Q*-switched neodymium:yttrium aluminum garnet (Nd:YAG) laser with a 150-ns pulse width and at a repetition rate of 12 kHz. Laser beam irradiation above about 6 J/cm^2 annihilated both thermal donors and stacking faults, giving evidence of melting and suggesting that the annihilation of the thermal donors and of the stacking faults can be useful in studying the surface morphology in laser/electron beam irradiation. (18 refs.)

72006 Amorphization of germanium, gallium phosphide, and gallium arsenide by laser quenching from the melt. A.G.Cullis, H.C.Webber, N.G.Chew (Royal Signals & Radar Establ., Malvern, England).
Appl. Phys. Lett. (USA), vol.42, no.10, p.875-7 (15 May 1983).
The direct formation of amorphous layers on (111) Ge, GaP, and GaAs crystals is demonstrated to occur when these are transiently melted with 2.5-ns UV laser pulses below particular radiation energy density thresholds. Above these thresholds, the melt resolidification rate is reduced and in each case the (111) crystals exhbit a transition to a regime of profuse twin defect nucleation. Also for each material, laser melting of (001) crystal leads to defect-free recrystallization when amorphization does not occur. All amorphous layers exhibit a cellular thickness modulation which may be due to a fundamental instability in the recrystallization interface. (18 refs.)

72007 Multimodal laser strength distributions for materials. Yu.A.Demochko, V.V.Azarov, I.E.Sidoryuk, L.A.Skvortsov, V.M.Shaposhnikov, E.V.Shcherbina.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.57-62 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1075-80 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
It is shown that a Weibull distribution applies to the laser strength of a material when this is restricted by defects of one type. Data are given on the polymodal distribution of the strengths of insulating coatings made of TiO_2, lithium niobate, KDP, and DKDP. (14 refs.)

72008 Changes in the physical properties and structure of a semiconductor produced by pulsed laser radiation. S.G.Kiyak (Inst. of Appl. Problems in Mech. & Math., Acad. of Sci., Ukrainian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.70-5 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1090-6 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
The basic trends in the interaction of a laser pulse with a semiconductor material are considered, including heating, melting, and epitaxial crystallization of the molten laser on a homosubstrate or heterosubstrate. (41 refs.)

72009 Features of laser damage to ferroelectric crystals. G.M.Zverev, V.S.Naumov, V.A.Pashkov, O.E.Sidoryuk, L.A.Skvortsov.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.109-13 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1135-40 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
A review is presented of the main results on laser damage to lithium metaniobate crystals. Results are presented on the damage to the surface and bulk of these crystals. Possible mechanisms are discussed that explain the features of laser damage to ferroelectric crystals. (8 refs.)

72010 Excitation of surface and waveguide modes by intense laser radiation and their effects on surface damage of condensed media. A.M.Bonch-Bruevich, M.K.Kochengina, M.N.Libenson, V.S.Makin, S.D.Pudkov, V.V.Turbaev.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.152-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1186-93 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
A physical model is proposed for the specific damage to the surface of a metal or a semiconductor produced by pulsed polarized laser radiation, which involves the formation of regular parallel damage bands. The model is based on the view that there is parasitic excitation of surface electromagnetic waves and of waveguide modes, whose interference with the incident radiation results in the spatially modulated temperature distribution. The model provides a nonconflicting interpretation of the available experimental data. (26 refs.)

72011 Mechanisms of laser damage to transparent polymer materials. V.S.Nechitailo (Lebedev Phys. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.159-63 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1194-9 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
Published mechanisms for large damage to transparent polymers are considered and it is shown that these mechanisms do not enable one to explain major features of the resistance of polymers on repeated irradiation. A mechanism is considered that involves absorbing defects, and a model for a defect is proposed as an inhomogeneous inclusion surrounded by the absorbing matrix. (23 refs.)

72012 Microdamage initiation in a transparent polymer on repeated laser irradiation. A.A.Manenkov, V.S.Nechitailo, A.S.Tsaprilov (Lebedev Phys. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.164-6 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1200-2 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
The trends in microdamage of size ~ 1 μm in polymethylmethacrylate PMMA and modified PMMA have been examined on repeated exposure to laser beams with wavelengths of 1.06, 0.69, and 0.53 μm. The spatial statistics of $P_\mu(N)$ have been examined and the dependence of the microdamage concentration on energy density has been determined for the various wavelengths and for specimen temperatures from 300 to 460K. (3 refs.)

72013 CW CO_2-laser annealing and alloying of semiconductors. Zou Shi-chang, Lin cheng-lu (Shanghai Inst. of Metall., Acad. Sinica, Shanghai, China).
Chin. Phys. (USA), vol.3, no.1, p.1-8 (Jan.-March 1983). [received: May 1983]
Annealing of the damaged layer of the ion-implanted semiconductors can be successfully achieved with the use of lasers, e.g. high intensity ruby-pulse laser, Nd:YAG laser and CW A^+ and Kr^+ lasers. However, a certain problem can occur when a laser is applied to semiconductor devices. For example the nonuniform reflectivity and absorption coefficients of the surface structure of semiconductor device can result in inhomogeneous annealing. The interference and the antireflection of SiO_2 in the multilayer structure of Si/SiO_2 could cause some local damage. Furthermore, owing to the relatively short absorption length of these lasers in silicon, the depth of annealing can also be subject to a certain limitation. In the west, there has been relatively very little publication about CO_2 laser annealing studies. Since 1979, the authors have carried out some work on the effect of the irradiation of semiconductors with CO_2 laser. In this paper, they focus on the discussion of the characteristics of CW CO_2 laser irradiation and its applications to the annealing of the damaged layer of ion-implanted Si and alloy formation on a GaAs surface. (17 refs.)

72014 Substrate heating effects in CO_2 laser annealing of ion-implanted silicon. M.Blomberg, K.Naukkarinen, T.Tuomi, V.-M.Airaksinen (Lab. of Phys., Helsinki Univ. of Technol., Espoo, Finland), M.Luomajarvi, E.Rauhala.
J. Appl. Phys. (USA), vol.54, no.5, p.2327-8 (May 1983).
A pulsed CO_2 laser has been used for the annealing of doped ion-implanted silicon crystals. Good recrystallization was achieved for a sample with a dopant density of 7×10^{15} cm^{-3}, when preheated to 850K. Damage caused by thermal runaway, however, made annealing of samples with a dopant concentration of this order difficult. The effect of the strong temperature dependence of the absorption coefficient at the CO_2 laser photon energy is considered. Melting model calculations give agreement with the experimental observations. (7 refs.)

72015 High-power laser radiation damage to transparent insulators. B.G.Gavrilov, V.I.Kulikov, V.V.Pedanov (O.Yu. Shmidt Inst. of Terrestrial Phys., Acad. of Sci., Moscow, USSR).
Sov. J. Quantum Electron. (USA), vol.12, no.11, p.1446-51 (Nov. 1982). Translation of: *Kvantovaya Elektron., Moskva (USSR)*, vol.9, no.11, p.2226-34 (Nov. 1982). [received: May 1983]
An experimental investigation was made of the kinetics of the post-breakdown phenomena accompanying the focusing of high-power laser radiation inside transparent insulators (using the example of single-crystal potassium alum). Measurements were made of the rate of growth of the damage region and of the propagation velocity of the elastic wave, its amplitude and wavelength. The dimensions of the breakdown region were compared with those of the damage zone in the insulator. An analysis was made of the laser radiation energy distribution in the observed phenomenon. 72017 Annealing of implantation defects in silicon through a quickly deflected electron probe. S.Panzer, R.Klabes.
Elektrie (Germany), vol.37, no.3, p.140-1 (1983). In German.
A method of the thermal annealing of implantation defects in semiconductors by means of an electron-beam is represented. Through an extremely quick time-linear periodically deflected electron probe a quasi-stationary line shaped surface limited high-temperature field in the semiconductor wafer is generated. The recrystallization of the implantation layer, being effected in the solid phase, takes place in implantation depths down to a few 1000 Å with a surface throughput of 10 cm^2 s^{-1}. (2 refs.)

72018 Irradiation induced precipitation in tungsten based, W-Re alloys. R.K.Williams, F.W.Wiffen, J.Bentley, J.O.Stiegler (Metals & Ceramics Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.655-66 (April 1983).
Tungsten-base alloys containing 5, 11, and 25 pct Re were irradiated in the EBR-II reactor. Irradiation temperatures ranged from 600 to 1500°C. All compositions were irradiated to fluences in the range 4.3 to 6.1×10^{25} n/m^2 ($E>0.1$ MeV), and three 25 pct Re samples were also irradiated to 3.7×10^{26} n/m^2 at temperatures 700 to 900°C. Postirradiation examination included measurement of electrical resistivity at room temperature and lower temperatures, X-ray diffraction, optical metallography, microprobe analysis, and transmission electron microscopy. Irradiation induced resistivity decreases observed in most of the samples suggested second-phase precipitation. Complete results confirmed the precipitate formation in all samples, in disagreement with exist-

ing phase diagrams for the W-Re system. Electron diffraction showed the precipitates to be consistent with the cubic, Re-rich χ-phase and inconsistent with the σ-phase. Large variations in precipitate morphology and distribution were observed between the different compositions and irradiation conditions. (40 refs.)

72019 Ion-beam damage in hollandite. J.C.Barry, J.L.Hutchison (Dept. of Metall. & Sci. of Materials, Univ. of Oxford, Oxford), R.L.Segall.
J. Mater. Sci. (GB), vol.18, no.5, p.1421-5 (May 1983).
The phenomenon of ion-beam damage in hollandite, first reported by Headley (1981) has been investigated in the hollandite phase in Synroc, and a related electron-beam damage phenomenon has been investigated in a synthetic barium aluminium hollandite. An explanation of the beam damage phenomena is proposed in terms of twinning in the monoclinic form of hollandite. (11 refs.)

72020 Computer simulation of pit formation in metals by ion bombardment. R.P.Webb, D.E.Harrison,Jr. (Naval Postgraduate School, Monterey, CA, USA).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1478-81 (9 May 1983).
Computer simulations of ion-bombardment events which recrystallize the target demonstrate pit formation at 1.0 keV. Atoms are ejected from the first two target layers in the pit region. The remainder of the pit is created by replacement-collision sequences. Linear-cascade and spike-regime events are dynamically indistinguishable. (19 refs.)

(see also 29.70 Energy loss and range relations)

72021 Charged-particle stopping in crystals. V.A.Khodyrev, E.I.Sirotinin (Inst. of Nuclear Phys., Moscow State Univ., Moscow, USSR).
Phys. Status Solidi b (Germany), vol.116, no.2, p.659-71 (1 April 1983).
The energy loss by a charged particle moving along a given path in the crystal lattice is calculated in terms of quantum perturbation theory. In calculating the contribution of excitations with low energy transfer, the sum rule is used. The highly-excited states are described in a quasi-classical approximation. The results obtained with those approximations coincide in the intermediate region of excitation energy. The results obtained allow the electrons of the core and the valence electrons to be treated from a unified standpoint. The averaging of the obtained expression for $\Delta E(b)$ over the random impact-parameter distribution leads to the Lindhard-Scharff formula (1953). The calculated dependence of the mean relative proton-energy loss upon the dechanneling depth is compared with available experimental data. (23 refs.)

72022 Theory of ionization of fast atomic particles in a crystal. V.A.Bazylev, A.V.Demura (I.V. Kurchatov Inst. of Atomic Energy, Moscow, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.371-9 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.688-83 (Aug. 1982). [received: May 1983]
A theory is developed for the ionization of atomic particles channeled by the interplanar potential of a crystal. With allowance for the thermal vibrations of the nuclei, the authors have studied the suppression of the probability of loss of electrons by an ion in elastic interaction with the lattice atoms both in channeling and in a disoriented crystal. An anomalous dependence of the ionization probability on the angle between the ion momentum and the axes (or planes) of the crystal is predicted. It is shown that, in contrast to the ionization of fast atomic particles in an amorphous material, in a crystal this process can occur as the result of inelastic interaction with the electron subsystem of the crystal. 62.10 MECHANICAL PROPERTIES OF LIQUIDS

(for viscosity of liquids, see 66.20)

72023 Flory theory and excess compressibilities of binary liquid mixtures containing one polar component. K.Subramanyam Reddy, P.R.Naidu (Chem. Lab., Sri Venkateswara Univ., Tirupati, India).
J. Acoust. Soc. India, vol.9, no.2, p.50-3 (April 1981). [received: March 1983]
Isentropic compressibilities K_S of binary liquid mixtures of benezene+benzonitrile, benezene+methylpropylketone and cyclohexane+methylpropylketone were determined at 303.15K. The deviation in isentropic compressibility, k_s is negative over the whole range of composition in the mixtures, benzene+benzonitrile and benzene+methylpropylketone and it is positive in the system, cyclohexane+methylpropylketone. Excess isothermal compressibilities were then calculated and the results were analysed in the light of the statistical theory developed by Flory. The analyses showed that the theory qualitatively predicts the excess function in the three binary mixtures. (8 refs.)

72024 Adiabatic compressibility of branched chain hydrocarbons—pentanes and hexanes. A.M.Awwad, R.A.Pethrick (Dept. of Pure & Appl. Chem., Univ. of Strathclyde, Glasgow, Scotland).
J. Mol. Liq. (Netherlands), vol.25, no.2, p.115-27 (April 1983).
Ultrasonic velocity and density measurements are reported on branched chain pentane and hexanes covering a temperature range 233 to 313K. The data are used to compute the Rao constant, the van der Waals b parameter and the free volumes. Interpretation of these parameters and the computed isothermal compressibilities are discussed with reference to the structure of molecules and the intermolecular interactions which occur in these systems. (22 refs.)

72025 Measurements of densities and dielectric constants of liquid propane from 90 to 300K at pressures to 35 MPa. W.M.Haynes (Thermophys. Properties Div., NBS, Boulder, CO, USA).
J. Chem. Thermodyn. (GB), vol.15, no.5, p.419-24 (May 1983).
Results of density and dielectric constant measurements on compressed liquid propane are reported. The results cover a temperature range from 90 to 300K at pressures to 35 MPa. The experimental densities and dielectric constants have been used to compute values for the Clausius-Mossotti function. (10 refs.)

72026 Apparent specific volumes of polymers in dilute solutions. D.Sarazin, J.Francois (Centre de Recherches sur les Macromolecules, CNRS, Strasbourg, France).
Polymer (GB), vol.24, no.5, p.547-52 (May 1983).
New results obtained on various polymers in solvents of differing molecular size and polarity confirm the dependence of their apparent specific volume ϕ_2 on polymer molecular weight and solvent molar volume. Existing models are discussed and a new model is proposed which assumes that ϕ_2 essentially depends on α, the expansion coefficient of the macromolecular coil, through the variation of the conformer sequence length in the chain. Some technical problems encountered with the vibrating tube densimeter are discussed. (34 refs.)

72027 Densities of liquid bismuth-silver and bismuth-cadmium alloys. K.Okajima, H.Sakao (Dept. of Metall., Nagoya Univ., Nagoya, Japan).
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.215-22 (April 1983).
A study was undertaken to examine whether or not the new method employing a modified picnometer can be applied up to high temperatures above 900K. The densities of the liquid bismuth-silver and bismuth-cadmium alloys were measured with a sufficient precision in the temperature range from 630 to 1323K. It was found out that a complicated dependence of the density of the excess molar volume on the composition resulted at all experimental temperatures, probably due to existence of the ordering in the liquid alloys. 62.20D Elastic constants

(see also 03.40D Mathematical theory of elasticity, 81.40J Elasticity and anelasticity)

72029 Elastic anomaly in $LiKSO_4$ crystals. M.E.M.Kassem, B.Mroz (Inst. of Phys., A. Mickiewicz Univ., Poznan, Poland).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.449-54 (April 1983).
The infra-low frequency elastic properties of ferroelastic $LiKSO_4$ crystals were studied in the temperature range from 100 to 300K, with the inverted torsion pendulum technique. Temperature variations of numerical values of the shear moduli G_x, G_y and G_z were found to be anomalous around the phase transition point of these crystals, at about 190K. From these measurments the temperature variations of elastic stiffnesses $c_{44}=c_{55}$ and c_{66} of $LiKSO_4$ crystals could be calculated. The latter, together with the results previously obtained from piezoelectric investigations, allowed the authors to calculate the temperature changes of the non-zero components of the elastic stiffness tensor of $LiKSO_4$ crystals. (14 refs.)

72030 Elastic and magnetoelastic effects in $TmAl_2$ and other $REAl_2$ compounds. C.Lingner, B.Luthi (Phys. Inst., Univ. Frankfurt, Frankfurt/Main, Germany).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.86-8 (April 1983).
The elastic constants of $TmAl_2$ have been determined as a function of temperature. The crystal field effects on the elastic constants are clearly observed. A comparison of elastic and magnetoelastic coupling constants for the $REAl_2$ compounds is also given. (14 refs.)

72031 Elastic-constant anomalies in metallic superlattices: a molecular-dynamics study. I.K.Schuller, A.Rahman (Materials Sci. & Technol. Div., Argonne Nat. Lab., Argonne, IL, USA).
Phys. Rev. Lett. (USA), vol.50, no.18, p.1377-80 (2 May 1983).
The elastic constants of Ni are calculated with use of molecular dynamics; at $\sim$5%[111] axial strain there is a large ($\sim$35%) softening of the C_{44} shear modulus and a stiffening of the in-plane Young's ($\sim$9.5%) and biaxial ($\sim$8%) moduli. These calculations are in remarkable agreement with experimental C_{44} for Mo/Ni superlattices. The experimentally observed transition to a highly disordered state occurs at the same strain value at which in the calculation the crystal becomes unstable. (15 refs.)

62.20F Deformation and plasticity

(inc. yield, ductility and superplasticity; see also 81.40L Deformation, plasticity and creep)

72032 Mechanical properties of metal/polymer composites. L.Nicodemo, L.Nicolais (Polymer Engng. Lab., Istituto di Principi di Ingegneria Chimica, Univ. of Naples, Naples, Italy).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.201-3 (May 1983).
The authors studied the mechanical properties of styrene-acrylonitrile polymer filled with iron and aluminium powders. The properties examined were stress/strain curves, elastic modulus, stress-at-break and elongation-at-break. It was found that poor adhesion occurred in composites with iron powders and no adhesion in composites with aluminium powders. (20 refs.)

72033 Topographic characteristics of superplastic deformation of two-phase brass. V.I.Portnoi, V.A.Kozhanov (Inst. of Steel & Alloys, Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.592-7 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the characteristics of the deformation relief of two-phase brass L59 in the course of superplastic deformation. New surface zones were found on grain boundaries oriented at right-angles to the stretching axis. Shear and bending of marker scratches near the grain boundaries were also observed. The displacement of the scratches and the width of the deformation zones were used to estimate the contributions of grain-boundary slip and of the diffusion creep to the total elongation. A correlation was found between the anisotropy of the relative elongation and the anisotropy of grain-boundary slip. (8 refs.) *A.T.*

72034 A micromechanical theory of grain-size dependence in metal plasticity. G.J.Weng (Dept. of Mech. & Materials Sci., Rutgers Univ., New Brunswick, NJ, USA).
J. Mech. & Phys. Solids (GB), vol.31, no.3, p.193-203 (1983).
The effect of grain-size on the elastoplastic behavior of metals is investigated from the micromechanics standpoint. First, based on the observations that dislocation pile-ups, formation of cell structures, and other inelastic activities influenced by the presence of a grain boundary actually take place transcrystallinely, a grain size dependent constitutive equation is proposed for the slip deformation of slip systems. By means of a modified Hill's self-consistent relation the local stress of a grain is calculated, and used in conjunction with this constitutive equation to evaluate the plastic strain of each constitutent grain. The grain-size effect on the plastic flow of polycrystals then can be determined by an averaging process. To check the validity of the proposed theory it was finally applied to predict the stress-strain curves and flow stresses of copper at various grain-sizes. The obtained results were found to be in good agreement with experimental data. (21 refs.)

62.20H Creep

(see also 81.40L Deformation, plasticity and creep)

72035 On the scaling behaviour in a log σ-log $\dot{\varepsilon}$ diagram. F.Povolo (Comision Nacional de Energia Atomica, Buenos Aires, Argentina), A.J.Marzocca.
J. Mater. Sci. (GB), vol.18, no.5, p.1426-32 (May 1983).
The significance of scaling behaviour in the creep and stress relaxation log σ-log $\dot{\varepsilon}$ curves is analysed. It is shown that such a property imposes some restrictions on the parameters of the theoretical models. Finally, the formalism is applied to some constitutive equations used in the literature to describe creep and stress relaxation data. (12 refs.)

72036 Theory of steady-state creep with a complex stress state. A.Yakovlyuk, E.Meleshko, S.Onopyuk (Belostok Polytech. Inst., Belostok, Poland).
Strength Mater. (USA), vol.14, no.5, p.598-602 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.28-31 (May 1982). [received: May 1983]
The theory is based on similarity of creep curves with different principal-stress ratios. An optimum method described for obtaining the equations makes it possible to adequately describe creep within a broad range of types of stress states on the basis of a limited amount of empirical data. Using the example of nodular iron, the existence is demonstrated of similarity among creep curves. (4 refs.)

72037 The role of microcracking during crack growth in brittle materials. E.Smith (Metall. Dept., Univ. of Manchester Inst. of Sci. & Technol., Manchester, England).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.204-6 (May 1983).
The author shows that microcracking away from the immediate vicinity of a crack tip in a brittle material, does not enhance J_{IC} because of the reduced elastic modulus within the outer zone of microcracks. Instead it is believed that microcracking is indicative of a distribution of failure stresses for the material elements, and this causes the crack front to become irregular, with a consequential increase in J_{IC}. Furthermore, this irregularity also leads to an enhanced resistance to crack growth. (13 refs.)

72038 A fracture mechanics analysis of indentation-induced Palmqvist crack in ceramics. K.Niihara (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.221-3 (May 1983).
A model is presented for Palmqvist cracks based on fundamental fracture mechanics principles. The K. Niihara et al. (1982) approach is re-established. Some theoretical foundation is given to empirical correction factor, $(H/E\phi)^{2/5}$ where H is hardness, E is Young's modulus and ϕ is the constraint factor. (18 refs.)

72039 Multiplicity of causes of grain-boundary fracture. A.S.Drachinskii (Inst. of Problems in Mateials Sci., Acad. of Sci., Ukrainian SSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.598-604 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
It is shown that grain-boundary fracture may be due to equilibrium and nonequilibrium segregation, and other structure states. For example, viscous grain-boundary structure is due to the hardening of grains in the presence of unhardened zones along the grain boundaries. In the case of brittle and viscous fracture along grain boundaries the proportion of the grain-boundary component depends on the ratio of the strength of a body to the strength of grain boundaries. The multiplicity of structure states that determine the strength and their combinations for the main body and grain boundaries are responsible for the great variety of causes of grain-boundary fracture. (35 refs.) *A.T.*

72040 The discreteness of fracture. G.I.Barenblatt.
Strength Mater. (USA), vol.14, no.5, p.695-9 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.107-10 (May 1982). [received: May 1983]
The main assumption of the theory of discreteness of fracture proposed by V.S. Ivanova (1975) is discussed and it is noted that the assumption is not theoretically justified and contradicts the available literature. (8 refs.)

72041 Comment on the article by G.I. Barenblatt 'The discreteness of fracture'. V.S.Ivanova.
Strength Mater. (USA), vol.14, no.5, p.699-701 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.111-13 (May 1982). [received: May 1983]
The criticism by G.I. Barenblatt (see ibid., vol.14, no.15, p.695, 1983) is reduced to the statement that the author of the reviewed studies does not know what theory and self-similarity are. If one examines the method of criticism used by Barenblatt, it must be said immediately that he does not know what fatigue and self-similarity are and, as indicated, is not familiar with the investigations carried out by G.C. Sih (1973) in which it was explained why the crack grows in a jumpwise manner. The fact that Barenblatt is not familiar with the special features of fatigue failure and uses incorrectly the concept of self-similarity has caused him to interpret incorrectly the concept of the discreteness and self-similarity of fatigue fracture. (14 refs.)

72042 Comment on the discreteness of fracture. G.I.Barenblatt.
Strength Mater. (USA), vol.14, no.5, p.702 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.113-14 (May 1982). [received: May 1983]
The author replies to V.S. Ivanova's reply (see ibid., vol.14, no.5, p.699, 1983) to his criticism (see ibid., vol.14, no.5, p.695, 1983) of her theory of discreteness of fracture. He justifies his criticism of this work. (no refs.)

72043 Reply to G.I. Barenblatt's comments [on 'the discreteness of fracture']. V.S.Ivanova.
Strength Mater. (USA), vol.14, no.5, p.703 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.114 (May 1982). [received: May 1983]
The authoress replies to the new comments of G.I. Barenblatt (see ibid., vol.14, no.5, p.702, 1983) and contends that they are of little significance because they contain no new criticism. (no refs.)

(see also 81.40P Friction, lubrication and wear)

72044 **The dependence of the friction coefficient on the crystal structure of solids: physical principles.** S.S.Karapetian, Yu.I.Korostelin (State Committee on Standards, Moscow, USSR).
Wear (Switzerland), vol.85, no.2, p.133-41 (1 March 1983).
The problem of contact interaction of pairs of the same pure metals with differing crystal structures was studied. The probability of formation of adhesive bonds, the formation of the true contact area and its dependence on the hardness of the metals and the atomic shearing force in the slip plane were investigated. Formulae were derived to calculate the friction coefficient and hardness of metals of various crystal structures in a wide temperature range from 0K up to temperatures close to the melting point. J. Phys. Colloq. (France), vol.43, no.C-9, p.485-8 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The authors have measured the elastic properties (sound velocity and internal friction) of glasses below 1K in the audiofrequency range (~1 KHz). The results obtained are discussed in the framework of the tunneling model of glasses. The major assumption of the tunneling model regarding tunneling states with long relaxation times has been verified. (5 refs.)

62.60 ACOUSTIC PROPERTIES OF LIQUIDS

(see also 62.80 Ultrasonic relaxation; for sound propagation, see 43.; for second sound in quantum fluids, see 67.40, 67.50 and 67.60)

72047 Acoustic and thermodynamic properties of some liquids on hard sphere model with attractive interactions. S.S.Bhatti (Dept. of Phys., Guru Nanak Dev. Univ., Amritsar, India), D.P.Singh.
J. Acoust. Soc. India, vol.9, no.2, p.39-43 (April 1981). [received: March 1983]
Ultrasonic velocity data available in the literature have been used to calculate isothermal compressibility, pseudo-Gruneisen parameter and Rao's acoustic constant as functions of temperature for seven pure liquids. The values of these parameters are compared with those computed from the alternative expressions obtained by Bhatnagar and Sharma (Ind. J. Pure Appl. Phys., vol.14, p.107, 1976) on the basis of the hard sphere model with attractive interactions. Surface tension, energy and Eotvos constant, expansivity and pressure coefficient of bulk modulus obtained on this model are compared with their experimental values. An explanation of the observed results is given in terms of molecular interactions in the liquids studied. (20 refs.)

72048 Ultrasonic behaviour of binary liquid mixtures of ethylenediamine with isoalcohols. D.N.Rao, A.Krishnaiah, P.R.Naidu (Dept. of Chem., Sri Venkateswara Univ. Coll. of Engng., Tirupati, India).
J. Acoust. Soc. India, vol.9, no.2, p.44-8 (April 1981). [received: March 1983]
Isentropic compressibilities, K_s of ethylenediamine+i-propanol, +i-butanol, and +i-pentanol were measured at 303.15 and 313.15K. The mixtures exhibit negative deviations in K_s. The negative deviation indicates that hydrogen bond interaction between unlike molecules dominates in the mixtures. Further, the negative deviation increases with increase in temperature. (11 refs.)

72049 Free volume of sodium chloride solutions in water-dimethyl formamide mixtures from ultrasonic velocity. S.O.Pillai, S.Natarajan, P.K.Palanisamy (Dept. of Phys., Coll. of Engng., Anna Univ., Madras, India).
J. Acoust. Soc. Am. (USA), vol.73, no.5, p.1616-18 (May 1983).
Free volume of sodium chloride solutions in water-dimethyl formamide mixtures have been evaluated using ultrasonic velocities from new formulas obtained by dimensional analysis. The results have been discussed in the light of existing theories. (6 refs.)

72050 Temperature dependence and asymmetry of the hypersound velocity in cyanobiphenyl liquid crystals. G.W.Bradberry, C.F.Clarke (Dept. of Phys., Univ. of Exeter, Exeter, England).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.305-8 (9 May 1983).
Measurements of the hypersound velocity have been made as a function of temperature for two principal directions in cyanobiphenyl samples. Velocity asymmetry is observed in both the nematic and smectic phases. The behaviour of the velocity in the vicinity of the phase-transition temperatures is discussed. (8 refs.)

(see also 62.80 Ultrasonic relaxation; for sound propagation, see 43.; for lattice dynamics and phonons, see 63.; for magnetoacoustic effects, see 72.55; for acoustoelectric effects, see 72.50; for acousto-optical effects, see 78.20H)

72051 Acoustic properties of a gadolinium single crystal in the region of magnetic phase transitions. D.I.Anikeev, L.K.Zarembo, S.N.Karpachev, I.K.Kumskova, O.D.Chistyakov, E.M.Savitskii (M.V. Lomonosov State Univ., Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.622-4 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The linear acoustic characteristics (absorption, velocity of sound) and the effective nonlinear elastic parameter were determined as a function of temperature in the range from liquid nitrogen to above 300K. Singularities of these properties were observed at a spin-reorientation temperature and at the Curie point. (8 refs.) *A.T.*

72052 An experimental investigation of pass bands and stop bands in two periodic particulate composites. V.K.Kinra (Aerospace Engng. Dept., Texas A&M Univ., College Station, TX, USA), E.L.Ker.
Int. J. Solids & Struct. (GB), vol.19, no.5, p.393-410 (1983).
An important property of periodic composites is that the dispersion curve is characterised by pass bands and stop bands. In the past these have been demonstrated, analytically and experimentally, for layered and fibrous composites. The purpose of the present experimental investigation is to show that the same phenomena exist in periodic particulate composites. The phase velocity of longitudinal waves through periodic particulate composites was measured as a function of frequency. Two composites were studied: (1) Glass spheres in an epoxy matrix and; (2) Steel spheres in a PMMA matrix. Two pass bands were observed in the first composite, whereas three pass bands could be identified in the second. The experimental technique employed was that of through-transmission of an ultrasonic pulse. (29 refs.)

72053 The scattering of ultrasonic waves by polycrystals. II. Shear waves. S.Hirsekorn (Fraunhofer-Inst. fur Zerstorungsfreie Prufverfahren, Univ. of Saarbrucken, Saarbrucken, Germany).
J. Acoust. Soc. Am. (USA), vol.73, no.4, p.1160-3 (April 1983).
For pt.I see ibid., vol.72, p.1021 (1982). The theory of ultrasonic propagation in polycrystals presented in a previous paper is used to calculate the scattering coefficient and the phase and group velocities of plane shear waves in polycrystals of cubic symmetry with randomly orientated grains. The calculation was done in second-order perturbation theory using the assumption that the changes in the elastic constants and in the density from grain to grain are small. The asymptotic values at low κa (Rayleigh scattering) are exactly the same as the well-known results from Bhatia and Moore. Numerical calculations are carried out for some examples. (4 refs.)

72054 Acoustic emission measurements of a shape-memory alloy. R.S.Geng, B.Britton, R.W.B.Stephens (Phys. Dept., Chelsea Coll., Univ. of London, London, England).
J. Acoust. Soc. Am. (USA), vol.73, no.4, p.1217-22 (April 1983).
A description is given of a systematic study of the acoustic emission (AE) characteristics of a specific shape-memory alloy, a copper-based Betalloy. Using a narrow-band AE measuring system, a considerable change in AE signals was observed in the different phase states of the Betalloy, the changes being particularly significant in the slope changes of the amplitude-distribution curves. By careful correlation of AE signals with the stress-induced martensitic transformation, it was found, in repetition cycles, that a reversible AE energy release accompanied the austenite-martensite transition process, which is in direct conflict with the 'Kaiser effect'. This observation implies that caution is necessary in applying the AE technique for evaluating failure in shape-memory alloys. The value derived from the AE data for the stress required to induce martensitic transformation and for the temperature at which the transformation is initiated are in good agreement with those obtained from stress-strain measurements. (8 refs.)

72055 Acoustical measurement of solid state non-linearity: application to $CsCdF_3$ and $KZnF_3$. M.A.Breazeale, J.Philip (Dept. of Phys., Univ. of Tennessee, Knoxville, TN, USA), A.Zarembowitch, M.Fischer, Y.Gesland.
J. Sound & Vib. (GB), vol.88, no.1, p.133-40 (8 May 1983).
Combination of the results of two sets of measurements on the same crystalline samples of $CdCdF_3$ and $KZnF_3$ has made possible the evaluation of the third-order elastic (TOE) constants of these two fluoroperovskites. In the first technique the hydrostatic pressure dependence of the velocity of ultrasonic waves of different propagation and polarization directions has been measured to determine three linear combinations of TOE constants. In the second technique the fundamental and the second harmonic amplitudes of an initially sinusoidal longitudinal ultrasonic wave of finite amplitude propagating along the principal directions have been measured to determine three other linear combinations. (33 refs.)

72056 Effect of the hydrogen tunnelling states of the acoustic wave propagation in niobium at low temperatures. G.Bellessa (Lab. de Phys. des Solides, Univ. Paris-Sud, Orsay, France).
J. Phys. Lett. (France), vol.44, no.10, p.L387-91 (15 May 1983).
The variation of the sound velocity at 200 MHz has been measured down to 50 mK in single crystals of niobium doped with oxygen and hydrogen. An effect of the hydrogen tunnelling states on the sound velocity is reported. Some characteristic parameters of these states are then deduced. (16 refs.)

72057 Pressure dependence of the low temperature acoustic anomalies in vitreous silica. U.Bartell, S.Hunklinger (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
J. Phys. Colloq. (France), vol.43, no.C-9, p.489-92 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The authors have measured the ultrasonic attenuation in quartz glass SUPRASIL W1 under high pressure (up to 4.2 kbar) down to temperature of 60 mK. At low temperatures (T<4K), contrary to their expectation, only a moderate increase of absorption (~25%) is observed. At higher temperature a strong rise of attenuation has been observed. (9 refs.)

72058 Connection between the low temperature acoustic properties and the glass transition temperature of fluoride glasses. P.Doussineau (Lab. d'Ultrasons, Univ. Pierre et Marie Curie, Paris, France), M.Matecki, W.Schon.
J. Phys. Colloq. (France), vol.43, no.C-9, p.493-6 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The variations of the velocity and the absorption of longitudinal and transverse acoustic waves have been measured in three fluoride glasses in the temperature range 0.1K to 1.5K. The density of states of two level systems (TLS) and the TLS-phonon coupling constants have been determined. The TLS density of states has been found to be inversely proportional to the glass transition temperature. (6 refs.)

72059 Ultrasonic study of lithium borate glasses. M.Devaud, J.-Y.Prieur (Lab. d'Ultrasons, Univ. Pierre et Marie Curie, Paris, France).
J. Phys. Colloq. (France), vol.43, no.C-9, p.497-500 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The authors present the results of an ultrasonic study of two fast ionic conducting glasses with compositions B_2O_3-0.5 Li_2O-0.7 LiCl and B_2O_3-0.5 Li_2O. The variation of the ultrasonic velocity is commented in structural terms. The comparison of the deduced values of the TLS parameters shows that they are independent of the composition. (5 refs.)

72060 Ultrasonic studies of some polymers at low temperatures. G.Federle, S.Hunklinger (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
J. Phys. Colloq. (France), vol.43, no.C-9, p.505-8 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The sound velocity and acoustic absorption have been measured in polymethylmethacrylate (PMMA), polyethylmethacrylate (PEMA), and polycarbonate (PC) from 60 mK to 10K. For all three polymers similar acoustic properties are observed. At low temperatures, in contrast to earlier measurements, the authors find an absorption proportional to $\omega^0 T^3$ and a logarithmic variation of the sound velocity, as expected from the tunneling model. At higher temperature the absorption reaches a plateau. This is for the first time the plateau, predicted in the tunneling model, has been observed in an amorphous material. (7 refs.)

72061 Acoustic propagation in an epoxy resin at very low temperatures. P.Doussineau, W.Schon (Lab. d'Ultrasons, Univ. Pierre et Marie Curie, Paris, France).
J. Phys. Colloq. (France), vol.43, no.C-9, p.509-11 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The attenuation and velocity changes of longitudinal acoustic waves in the 150-2140 MHz range have been measured in an epoxy resin in the temperature range 0.1K to 10K. The behaviour usually seen in amorphous insulators were observed: in particular the T^3 variation of the attenuation at the lowest temperatures, logarithmic increase of the velocity. All the features are well explained in the framework of the TLS model. (7 refs.)

72062 Glass-like anomalies in the hypersonic properties of OH^- doped KCl crystals. R.Vacher, J.Pelous, J.F.Berret (Lab. de Spectrometrie Rayleigh-Brillouin, Univ. de Montpellier II, Montpellier, France), M.Schmidt.
J. Phys. Colloq. (France), vol.43, no.C-9, p.517-19 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
Using the Brillouin scattering technique, the authors have measured the velocity and attenuation of 30 GHz longitudinal hypersonic waves down to 1K for OH^- doped KCl crystals: they present here the results for a sample with OH content of 0.5%. They have observed an absorption peak in the vicinity of 20K. At lower temperature, the attenuation increases with decreasing temperature. These results can be described by assuming a coupling of phonons with tunneling systems and thermally activated defects, related to OH^- impurities. (9 refs.)

63.00 LATTICE DYNAMICS AND CRYSTAL STATISTICS

(see also 05.50 Lattice theory, 65. Thermal properties, 66.70 Thermal conduction, 68.30 Dynamics of surface and interface vibrations, 78.30 Infrared and Raman spectra)

63.10 GENERAL THEORY

72063 Bond dynamics in arbitrary lattices. D.C.Mattis (Phys. Dept., Univ. of Utah, Salt Lake City, UT, USA).
Phys. Lett. A (Netherlands), vol.95A, no.2, p.101-3 (18 April 1983).
The author treats the quantum mechanics/dynamics of lattices in arbitrary dimensions, with arbitrary topology—whether crystalline or amorphous—whether elastic or inelastic. The method is a generalization of a transformation which has been successful for one- or two-dimensional structures, from site to bond coordinates. The author's formulation clarifies the role of defects in melting phenomena. (4 refs.)

63.20 PHONONS AND VIBRATIONS IN CRYSTAL LATTICES

72064 Concentration dependence of the local oscillation spectrum in V-Be α solutions. Yu.L.Shitikov, N.A.Chernoplekov, M.G.Zemlyanov, A.P.Zhernov (I.V. Kurchatov Inst. for Atomic Energy, Moscow, USSR).
J. Phys. C (GB), vol.16, no.13, p.2471-9 (10 May 1983).
Cold neutron inelastic scattering is used to investigate the dynamics of α solutions of Be in a V matrix for various concentrations. The increase of Be concentration leads to a broadening of the local oscillation (LO) spectrum and to a shift of its centre. The concentration dependence of the LO spectrum width and LO energy position, as well as the deformation of the lattice vibrations spectrum are compared with calculations in terms of the coherent potential approximation. (15 refs.)

72065 Excitation wavenumber dependence of the symmetric chain-stretching mode of linear-chain mixed-valence platinum complexes. R.J.H.Clark, M.Kurmoo (Christopher Ingold Labs., Univ. College London, London, England).
J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.4, p.519-27 (April 1983).
The wavenumber ν_1, of the symmetric chain-stretching mode of linear-chain halogen(X)-bridged mixed-valence complexes of platinum increases as the wavenumber of the excitation line (ν_0) increases, whereas those of equatorial modes do not. For any set of complexes the wavenumber change, $\nu_1(\lambda_0$=short wavelength)$-\nu_1(\lambda_0$=long wavelength), increases in the order Cl<Br<I and is largest for those complexes in which the $Pt^{II}...Pt^{IV}$ separation is least and for which the bond-length ratio $r(Pt^{IV}-X)/r(Pt^{II}-X)$ is nearest to unity. This suggests that the wavenumber dispersion of ν_1 with ν_0 depends on the extent of valence delocalisation along the chain. (18 refs.)

72066 One-dimensional quantum-spin-phonon solitons. A.Messina (Istituto di Fisica, Univ. degli Studi di Palermo, Palermo, Italy).
Phys. Rev. B (USA), vol.27, no.8, p.4665-83 (15 April 1983).
The quantum dynamics of a compressible harmonic chain of N two-level atoms strongly interacting with the phonons of the lattice is investigated. Two types of mixed excitons are discussed which propagate through the lattice exhibiting solitonic properties. The first type of solitonlike excitation describes the motion of the wall separating two magnetoelastic domains. This transports less energy than the second type of solitonlike excitation which describes the motion of a single spin reversal in the chain. An explicit expression is obtained for the speed of these excitations as a function of an appropriate shape parameter h. These results are obtained by approximate self-consistent integration of a system of nonlinear differential equations related to the Heisenberg equations of motion for atomic operators. (21 refs.)

63.20M Phonon-defect interactions

72068 **Strain-field scattering of phonons: some comments on papers by Kogure and Hiki.** R.A.Brown (Jabatan Fizik, Univ. Pertanian Malaysia, Selangor, Malaysia).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1498-9 (April 1983).
Early calculations of phonon scattering by the strain fields of crystal imperfections employed drastic approximations which left the results uncertain. Important advances were made by Kogure and Hiki (see ibid., vol.36, p.1597, 1974, and ibid., vol.38, p.471, 1975) who combined an exact description of the (long-wave) phonon-strain interaction with realistic phonon dispersion relations. The author discusses corrections to the calculations of Kogure and Hike. (16 refs.)

72069 **Reply to the comment 'Strain-field scattering of phonons'.** Y.Kogure, Y.Hiki (Tokyo Inst. of Technol., Tokyo, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1500-1 (April 1983).
The authors reply to the comments of R.A. Brown (see ibid., vol.52, no.4, p.1498, 1983) on their previous work (see ibid., vol.36, p.1597, 1974, and ibid., vol.38, p.471, 1975). The topic is phonon scattering in anisotropic medium. The authors have previously developed a precise calculation of strain-field scattering of phonons in an anisotropic crystal and obtained a general formula for the strength of the scattering. The formula was applied to phonon scattering by a crystal dislocation.

63.50 VIBRATIONAL STATES IN DISORDERED SYSTEMS

72070 **Phonons in amorphous materials.** S.Hunklinger (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
J. Phys. Colloq. (France), vol.43, no.C-9, p.461-74 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The study of the propagation of phonons is an important tool to investigate the sometimes unexpected and puzzling dynamic properties of amorphous solids. At first, as a typical example, the author discusses the acoustic properties of vitreous silica. In the second part of the review emphasis will be given to the anomalous low temperature properties of amorphous materials. (51 refs.)

72071 **Thermoelastic and relaxational properties of dielectric and metallic glasses at low temperature.** H.Tietje, M.von Schickfus, E.Gmelin (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
J. Phys. Colloq. (France), vol.43, no.C-9, p.529-32 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The authors have investigated the low-temperature Gruneisen parameter and the long-time relaxational behaviour of the tunneling excitations in vitreous silica and in the metallic glass PdSiCu through the thermoelastic effect. In the case of a-SiO_2, the data agree qualitatively with previous measurements of the thermal expansion, and relaxation times of up to 600 s have been detected. For PdSiCu a large relaxational contribution was found. (6 refs.)

72072 **The effect of structural disorder on phonon lifetimes.** D.Walton, J.J.Vanderwal, H.C.Teh (Phys. Dept., McMaster Univ., Hamilton, Ontario, Canada).
J. Phys. Colloq. (France), vol.43, no.C-9, p.545-8 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The lifetimes of thermal phonons in fused silica have been measured using Brillouin spectroscopy. The results show that in addition to that due to two level systems there is a substantial contribution to the scattering which is temperature independent and is propably structural in origin. (9 refs.)

72073 **On the Debye-Waller factor of BCC transition metals.** A.R.Jani, V.B.Gohel (Dept. of Phys., Sardar Patel Univ., Gujarat, India).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.469-78 (April 1983).
Debye-Waller factors at different temperatures for six BCC transition metals have been calculated on the basis of a screened shell phenomenological model proposed by the authors. Comparison of theoretical values with the existing experimental data is made and discussed. The computed values for X-ray characteristic temperatures (Θ_M) are also compared with those resulting from general force constant models determined by inelastic neutron scattering experiments. (66 refs.)

72074 **X-ray determination of the mean-square atomic displacement and associated Debye temperature of erbium.** N.Gopikrishna, D.B.Sirdeshmukh (Dept. of Phys., Kakatiya Univ., Warangal, India).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K105-8 (1 April 1983).
The results of an X-ray determination of the Debye-Waller factors, RMS amplitudes of vibration, and the Debye temperature are reported. The value obtained by the X-ray method is found to be lower than that from specific heat and also from elastic constant. (8 refs.)

72075 Application of an approximate form of spacing statistics to the high-temperature thermodynamic properties of UO_2. L.Manes, V.Dallacasa, B.Leonardis (Commission of the European Communities Joint Res. Centre, Karlsruhe Establ., European Inst. for Transuranium Elements, Karlsruhe, Germany).
High Temp.-High Pressures (GB), vol.14, no.4, p.449-63 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
A short survey of spacing statistics is given. It is shown that an equation of state derived by use of these statistics predicts properties at the triple and critical points of many elements and compounds which are in reasonable agreement with experimental data. The method has been applied to uranium dioxide. (13 refs.)

72076 Thermodynamic properties of liquid thorium monocarbide up to the critical point. G.Gigli, M.Guido, G.De Maria (Istituto di Chimica Fisica, Univ. di Roma, Rome, Italy).
High Temp.-High Pressures (GB), vol.14, no.4, p.465-75 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
The equation of state of liquid thorium monocarbide has been evaluated by an application of the significant structures theory, which takes into account the complex vaporization behaviour of this substance. In addition to the critical parameters and the thermodynamic properties along the liquid-vapour line a representation of the pressure-internal-energy relationship is given for a wide range of densities. (29 refs.)

72077 Algebraic investigations in Landau model of structural phase transitions. I. Group lattices and lattices of stability spaces. V.Kopsky (Inst. of Phys., Czechoslovak. Acad. Sci., Praha, Czechoslovakia).
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.5, p.485-509 (1983).
An abstraction from actual physical situations and from the meaning of parameters which appear in the phase transition theory leads to an algebraic study, the main object of which are the group-subgroup relations and the subduction of the identity representation. Subgroups of the initial group G form an algebraic structure called the lattice of the group G. To a symmetry descent from G to its subgroup F there corresponds an onset of those variables which belong to the stability space of the group F. It appears that these stability spaces form a lattice dual to the lattice of the group G. An important concept of exomorphism of group-subgroup relations is introduced and analysed. If two symmetry descents (group-subgroup relations) $G|F$ and $\bar{G}|\bar{F}$ are exomorphic, then all aspects of the subduction of the identity representation are quite similar in both cases. The group lattices and lattices of stability spaces as well as all the exomorphic types of group-subgroup relations within the crystal point groups are given in appendix. (24 refs.)

72078 Fluctuations in the interface between two phases. F.Schlogl, C.Escher (Inst. fur Theoretische Phys., Tech. Univ., Aachen, Germany), R.S.Berry.
Phys. Rev. A (USA), vol.27, no.5, p.2698-704 (May 1983).
In continuation of an earlier paper [F. Schlogl and R.S. Berry, Phys. Rev. A 21, 2078 (1980)] (referred to as I), small fluctuations in the interface between two phases will be discussed and with this an error in I will be corrected. The dynamics of the fluctuations is connected with the quantum mechanics of the modified Poschl-Teller potential. Moreover, the fluctuations in the solitary solution of a moving surface are studied and also brought into connection with a quantum-mechanical system. The regression spectrum of these fluctuations is discussed in dependence on the velocity of the interface. If this velocity exceeds a certain value, the character of the regression to the kink profile changes qualitatively. (6 refs.)

72079 Undercooling behavior of liquid metals. J.H.Perepezko, J.S.Paik (Dept. of Metall. & Mineral Engng., Univ. of Wisconsin-Madison, Madison, WI, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.49-63
The undercooling of liquid metals is often observed, but is restricted by the catalysis of the most potent heterogeneous nucleation site in contact with the liquid. An experimental approach that yields large undercoolings involves the slow cooling from the melt of a dispersion of stabilized fine liquid droplets. Droplet studies have extended measurements of the undercooling limit for low melting point metals to the range of 0.3 to 0.4 T_m. In droplets, surface coating and size characteristics usually limit the undercooling and control the uniformity of crystallization behavior. A nonuniform undercooling behavior can produce microstructural variations in powder samples with respect to metastable phases and solute segregation, but these variations can be diminished for isenthalpic solidification of hypercooled liquids. In alloys, the trend in nucleation temperature can follow a similar pattern as the composition dependence of the liquidus. With highly undercooled droplets, and even at modest ΔT with known heterogeneous sites, structural modifications such as extended solid solutions and metastable intermediate phases can be generated which are similar to those produced by rapid quenching techniques. These features highlight the importance of a high liquid undercooling as well as a high cooling rate in promoting effective rapid solidification processing treatments. (25 refs.)

64.70 PHASE EQUILIBRIA, PHASE TRANSITIONS, AND CRITICAL POINTS

(see also 81.30 Phase diagrams and microstructures developed by solidification and solid-solid phase transformations)

72080 Comment on 'nomenclature and geometrical representation of invariant equilibria in multicomponent systems [and reply]. A.Prince (General Electric Co., Hirst Res. Center, Wembley, England), N.Kanani, J.Lohberg.
Z. Metallkd. (Germany), vol.74, no.5, p.338 (May 1983). In English, German.
Comments are made on a paper by Lohberg and Kanani (see ibid., vol.73, p.619, 1982). It seems doubtful whether the approach of Lohberg and Kanani advances the representation of multicomponent invariant equilibria and their associated monovariant equilibria. Invariant reactions are classified as belonging to three types: invariant formation equilibrium: invariant decomposition equilibrium and invariant transition equilibrium. This classification is unnecesary. The generalised invariant equilibrium for isobaric sections of n-component systems, which contain $(n+1)$ phases, can be represented in the following form: ${}_{\phi 1}+{}_{\phi 2}+\ldots{}_{\phi i-1}+\leftrightarrows{}_{\phi i+1}+\ldots+{}_{\phi n}+{}_{\phi n}+{}_{1}$. For i=n, an invariant formation equilibrium is established. For $i=1$, an invariant decomposition equilibrium is established. Kanani and Lohberg reply stating that it does not matter which type of distribution is chosen, as long as there is agreement. They also point out that Prince's equation are not mathematically correct. (2 refs.)

72081 Heat of crystallization and melting point of amorphous silicon. E.P.Donovan, F.Spaepen, D.Turnbull (Div. of Appl. Sci., Harvard Univ., Cambridge, MA, USA), J.M.Poate, D.C.Jacobson.
Appl. Phys. Lett. (USA), vol.42, no.8, p.698-700 (15 April 1983).
Thin layers of amorphous silicon (a-Si) were produced by noble gas ion implantation of (100) substrates held at 77K. Rutherford backscattering and channeling, and differential scanning calorimetry were used to measure the heat of crystallization, ΔH_{ac}, to be 11.9 ± 0.7 kJ/mol, substantially less than the value predicted by scaling ΔH_{ac} of a-Ge. The crystal growth velocity is found to have the form $\nu=\nu_0\exp(-2.24\text{ eV/kT})$. The authors obtain a new estimate, 1420K, for the melting temperature of a-Si. (26 refs.)

72082 Direct observation of time-temperature-transformation curves for crystallization of ice from solutions by a homogeneous mechanism. D.R.MacFarlane, R.K.Kadiyala, C.A.Angell (Dept. of Chem., Purdue Univ., West Lafayette, IN, USA).
J. Phys. Chem. (USA), vol.87, no.7, p.1094-5 (31 March 1983).
Emulsified samples of aqueous solutions of lithium chloride have been rapidly cooled to temperatures in the vicinity of the 'homogeneous nucleation temperature' T_g and observed isothermally in a differential calorimeter to identify the time delay before the maximum crystallization rate (detected by the release of the heat of crystallization) is achieved. The locus of the times t_p to reach the maximum rate at different temperatures has the classic form of the time-temperature-transformation (TTT) curve described in theories of homogeneous nucleation and growth. The displacement of this TTT curve to longer times and lower temperatures can be observed by increasing the solution concentration. The results correlate well with much longer time observations made recently with electrical conductivity studies of thin bulk samples near their glass transition temperature. (13 refs.)

72083 Melting and crystallisation on a corrugated surface. P.Vashista (Argonne Nat. Lab., Argonne, IL, USA), R.K.Kalia, J.J.Quinn.
J. Phys. C (GB), vol.16, no.13, p.L405-10 (10 May 1983).
Melting and crystallisation of a triangular electron solid on a commensurate, sinusoidally corrugated surface (of wavelength $\lambda=\sqrt{3}a/2$, a=lattice spacing) are studied by the molecular dynamics method. If the height of the corrugation $U_0$is less than a certain critical value U_c, melting is found to be a grain-boundary-mediated first-order transition. However, for $U_0>U_c$ the transition is continuous and induced by a small density of defects. (20 refs.)

72084 Volume dependence of the melting temperature for alkali metals with Debye's model. T.Soma, H.-M.Kagaya, M.Nishigaki (Dept. of Appl. Phys. & Math., Akita Univ., Akita, Japan).
Phys. Status Solidi b (Germany), vol.116, no.2, p.673-6 (1 April 1983).
Using the volume-dependence of the Gruneisen constant at higher temperatures, the volume effect on the melting temperature of alkali metals is studied by Lindeman's melting law and Debye's model. The obtained melting curve increases as function of the compressed volume and shows the maximum of the melting point at the characteristic volume. The resultant data are qualitatively in agreement with the observed tendency for alkali metals. (10 refs.)

72085 Mechanisms for melting. S.T.Chui (Bartol Res. Found., Franklin Inst., Univ. of Delaware, Newark, DE, USA).
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.29-42
Melting is one of the most general phenomena that is not completely understood. Much interest is revived in this subject recently because of the belief that topological defects may play a significant role. The effect of these topological defects is simpler to treat in two dimensions (2D) and this is the focus of the present review. The author also comments on the situation in three dimensions (3D) and the question of glasses at the end. (28 refs.)

72086 Melting and freezing in two dimensions: a molecular dynamics study. P.Vashishta, R.K.Kalia (Argonne Nat. Lab., Argonne, IL, USA).
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.43-73
Using the molecular dynamics technique, the authors have investigated the nature of melting and freezing transitions as well as structural and dynamical properties of liquid and solid phases in two-dimensional systems interacting via $1/r$ and $1/r^3$ potentials. From the velocity autocorrelation function (VAF) and dynamic structure factor for the electron liquid, it is shown that the well-defined oscillations in VAF are due to a coupling between the single particle motion and longitudinal excitations of wavevector on the order of the inverse interparticle separation. (54 refs.)

72087 Melting, order, flows, mappings and chaos. M.E.Fisher, D.A.Huse (Baker Lab., Cornell Univ., Ithaca, NY, USA).
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.259-93
A difficulty in reliably diagnosing continuous melting transitions via canonical simulations is pointed out and illustrated by the model of hard hexagons on a plane triangular lattice; finite-sized realizations at fixed density may well exhibit coexisting ordered and disordered peaks in phase space even when the transition is continuous in the thermodynamic limit. The role of flows and mappings in the theory of phase transitions is discussed. The nature of the phase diagrams in model systems displaying spatially modulated order and commensurate-incommensurate transitions is emphasized and some recent developments are reviewed briefly. (71 refs.)

72088 Growth kinetic limitations during rapid solidification. W.J.Boettinger (Metall. Div., NBS, Washington, DC, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.15-31
The importance of growth kinetics in the development of the microstructure of rapidly solidified alloys is described. Growth kinetics are conveniently divided into diffusion kinetics and interface attachment kinetics. The former, which are used extensively for the analysis of slow rate solidification, can be extended to high solidification rates to predict some microstructural features; e.g., the limitations on eutectic growth rate which can promote the formation of a metallic glass, and the reduction of microsegregation. At the highest rates, interface attachment kinetics must be included. Some microstructural effects of the velocity dependence of the partition coefficient are described. (60 refs.)

72089 Solidification mechanism of highly undercooled metal alloys. Y.Shiohara, M.G.Chu, D.G.MacIsaac, M.C.Flemings (MIT, Cambridge, MA, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.65-9
Describes the results of experiments on metal droplet undercooling, and presents a preliminary analysis of the structures obtained. Work was conducted with Sn-25 wt.%Pb and Ni-34 wt.%Sn alloys. To achieve the required high degrees of undercooling, emulsification treatments were utilized. Experiments show the fraction of supersaturated primary phase is found to be a function of the amount of undercooling, as is the fineness of the structures. The solidification behavior of the tin-lead droplets during recalescence was analyzed using three different hypotheses; 1) solid forming throughout recalescence is of the maximum thermodynamically stable composition, 2) partitionless solidification below the 'T_0' temperature, and solid forming thereafter is of the maximum thermodynamically stable composition, and 3) partitionless solidification below the 'T_0' temperature with solid forming thereafter that is of the maximum thermodynamically metastable composition that is possible. (7 refs.)

72090 Morphological stability of electron beam melted aluminum alloys. R.J.Schaefer, S.R.Coriell, R.Mehrabian, C.Fenimore, F.S.Biancaniello (NBS, Washington, DC, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.79-89
For constant velocity solidification, morphological stability theory delineates the temperature gradients required for plane front solidification of a specific alloy. Using electron beams, surface heating of metals can be carried out with sufficiently well characterized thermal input to permit reliable use of computer models of melting and solidification. From numerical calculations, the growth velocity and temperature gradients as a function of position during resolidification can be obtained; combining these results with morphological stability theory indicates the resolidification regimes for which the plane front is unstable. Presumably, completely planar solidification may be attained by selecting heating modes such that the region of instability is totally avoided, but the expected interface morphology is more difficult to predict if the interface passes briefly through an unstable region and then re-enters a region of stability. Aluminum-silver and aluminum-manganese alloys were melted under an electron beam with particular emphasis on attaining solidification sufficiently rapidly to satisfy the gradient-independent absolute stability condition. The velocities required to produce stability were considerably larger than expected. (11 refs.)

72091 A molecular orbital model of melting and glass formation. M.E.Eberhart, K.H.Johnson, R.C.O'Handley (MIT, Cambridge, MA, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.103-8
SCF-Xα-SW calculations have been performed on the glass forming crystal of Ni_2B. The resulting molecular orbital topology near the Fermi level is similar to that previously obtained by SCF-Xα-SW calculation on the glass forming crystals of Pd-Si and Cu-Zr. These similarities, it is conjectured, indicated melting is an electronically driven phase transition and that liquid and glass structures are more the result of electronic than kinetic factors. It is shown that the molecular orbital model of melting in transition metals generates structures similar to those resulting from the dense random packing of hard spheres method, and the molecular orbital mechanism admits, in a qualitative way, the explanation of a broad range of liquid and glass properties. (12 refs.)

64.70F Liquid-vapour transitions

72092 Interpretation of laser pulse heating experiments for determination of vapour pressures of nuclear fuel materials at high temperatures. J.Magill, C.Cercignani, R.W.Ohse (Commission of the European Communities Joint Res. Centre, Karlsruhe Establ., European Inst. for Transuranium Elements, Karlsruhe, Germany).
High Temp.-High Pressures (GB), vol.14, no.4, p.441-8 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
A theoretical analysis is presented of the different measurement techniques (depth measurement, recoil, and Mach disk techniques) used to determine the high-temperature saturated vapour pressure of nuclear fuel materials UO_2, $(UPu)O_2$, and UC by the laser pulse heating method. It is shown that the use of the Hertz-Knudsen equation relating the rate of evaporation to the saturated vapour pressure is basic to each of the three techniques, and that this equation is used as a boundary condition in the gas dynamic modelling of the structure of the vapour jet. The particular gas dynamic models used are analysed in detail and conclusions are drawn on the relative merits of the individual techniques. (14 refs.)

72093 High-temperature vaporization and thermodynamics of the titanium oxides. XVII. Approximate oxygen potentials in metal-rich solutions. B.Granier, P.W.Gilles (Dept. of Chem., Univ. of Kansas, Lawrence, KS, USA).
High Temp.-High Pressures (GB), vol.14, no.4, p.383-6 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
Measures the oxygen potential in metal-rich titanium-oxygen alloys at much higher temperatures than have been previously used, as a preliminary to an investigation at even higher temperatures with liquid samples. Samples with normal compositions in the range O/Ti=0.065-0.851 were prepared by arc melting. Vaporization was studied in a single-focusing mass spectrometer in which the intensities of TiO^+ and Ti^+ were measured at different temperatures in the range 1693-1893K for each of four samples, by use of a computer-based data-acquisition and equipment-control system. Approximate pressures of TiO(g) and Ti(g) were obtained from the measurements, and the approximate monatomic oxygen potentials, as obtained from the ratios of these pressures and known thermodynamic values, are of the order of 10^{-17} atm. (11 refs.)

72094 High-temperature vaporization of calcium oxide. T.Sata, T.Sasamoto, K.Matsumoto (Res. Lab. of Engng. Materials, Tokyo Inst. of Technol., Yokohama, Japan).
High Temp.-High Pressures (GB), vol.14, no.4, p.399-408 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
Langmuir vaporization of CaO in vacuum was measured at 1500-1900°C; vapour pressures of the main species Ca(g) were obtained. The vaporization coefficient was found to be almost unity up to 1800°C. Vaporization of CaO in O_2-Ar atmospheres containing H_2O vapour was measured at 1405-1743°C by means of the transpiration method. It was concluded that the main species under these conditions was $Ca(OH)_2(g)$. The equilibrium constant, K_p, and standard enthalpy change for the reaction $CaO(s)+H_2O(g)\rightleftharpoons Ca(OH)_2(g)$ were calculated. From these values, a dissociation energy for $Ca(OH)_2(g)$ of

206.4 kcal mol^{-1} was obtained, and it agreed well with values obtained from flame spectrometry. Four sets of vapour pressures for Ca(g), CaO(g), CaOH(g), and $Ca(OH)_2$(g) over CaO(s) are shown for four different combinations of $P(O_2)$ and $P(H_2O)$. (16 refs.)

72095 New pulse counting method for the improvement of the sensitivity and precision of vapour-pressure measurements. M.Yamawaki, M.Yasumoto, C.Nakano (Res. Center for Nuclear Sci. & Technol., Univ. of Tokyo, Tokyo, Japan), M.Kanno.
High Temp.-High Pressures (GB), vol.14, no.4, p.423-30 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
A method for pulse counting by the modulation of neutral beams has been developed to improve the sensitivity of the measurement of vapour pressures. This system can compensate for background pulses in intervals as short as 8 ms, so that the detection limit of vapour pressure has been improved by more than two orders of magnitude compared with the conventional DC method. A new method of measuring electron-multiplier counting efficiency has also been developed to improve the precision of the measurements. This method makes use of a pulse-height analyser and a Faraday cup. With this system, the counting efficiencies of H_2^+ and H_2O^+ ions were found to have a value of ~1.1, while those of the other atomic vapour species were close to unity at an incident ion energy higher than ~7 keV. 72096 Phase transition in a solution of heteropolymers. E.S.Nikomarov (L.D. Landau Inst. of Theoretical Phys., Acad. of Sci., USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.310-15 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.564-75 (Aug. 1982). [received: May 1983]
A two-field model is set up which describes a binary solution of linear heteropolymers in chemical equilibrium. The region of low concentrations and large mean molecular lengths is investigated. It is shown by the renormalization group method that in first-order approximation in ϵ a phase transition of first order in the monomer activity occurs in the solution. It is also shown that a sufficiently long heteropolymer molecule in such a solution forms a globule. Results are presented of calculations for a solution containing cyclopolymers. (9 refs.)

72097 Free energy expansion for the two-component order parameter. R.Sikora (Inst. of Math. & Phys., I. Lukasiewicz Tech. Univ., Rzeszow, Poland), K.Parlinski.
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.479-84 (April 1983).
An analysis of the free energy expansion from the point of view of the first order structural phase transition is performed. The external lines along which the order parameter changes and the expansions of the free energy along these lines are given. (7 refs.)

72098 Order-disorder transitions and solid state reaction kinetics in Na_2SO_4-K_2SO_4 system. I. M.S.Kumari, E.A.Secco (Dept. of Chem., St. Francis Xavier Univ., Antigonish, NS, Canada).
Can. J. Chem. (Canada), vol.61, no.3, p.594-8 (March 1983).
The physicochemical aspects of the order-disorder phase transitions occurring in the Na_2SO_4-K_2SO_4 system were investigated by thermal analyses, infrared absorption, and X-ray diffraction methods. Kinetic and structural studies on the compounds $KNaSO_4$ and $K_3Na(SO_4)_2$ are reported in more detail. (19 refs.)

72099 Electrical conductivity and phase transition studies on pure and doped (Cd^{2+}, Gd^{3+}) $KNaSO_4$ and $K_3Na(SO_4)_2$. II. M.S.Kumari, E.A.Secco (Dept. of Chem., St. Francis Xavier Univ., Antigonish, NS, Canada).
Can. J. Chem. (Canada), vol.61, no.3, p.599-601 (March 1983).
For pt.I see ibid., vol.61, no.3, p.594-8 (1983). Electrical conductivity measurements on pure and doped $KNaSO_4$ and $K_3Na(SO_4)_2$ reveal high ionic conductivity values in the high temperature phase. High conductivity values ascribed to Na^+ resemble a superionic or fast-ion conductor. (12 refs.)

72100 Incommensurate structures induced by an external field and the soft mode concept. I.M.Vitebskii (Physicotech. Inst., Acad. of Sci., Donetsk, Ukrainian SSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.468-71 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The soft mode concept is used to study the situation when the appearance of a long-period incommensurate structure in an external field is unavoidable on the basis of general symmetry considerations. Two qualitatively different possibilities are considered and these occur in the case of random and special orientations of an external field relative to the crystallographic axes. The symmetry aspects of the influence of an external field on an incommensurate structure are considered for the case when such a structure forms as a result of a second-order transition from a homogeneous phase. (5 refs.) *A.T.*

72101 Structural relationships between spontaneous strain and acoustic properties in ferroelastics. W.I.F.David (Clarendon Lab., Oxford Univ., Oxford, England).
J. Phys. C (GB), vol.16, no.13, p.2455-70 (10 May 1983).
A number of structural relationships between the spontaneous strain and acoustic properties of ferroelastic materials is described. Zero-velocity pure transverse acoustic modes are shown to occur in mutually perpendicular pairs at second-order phase transitions. These soft modes have propagation and displacement directions situated in ferroelastic domain wall planes. The resultant ferroelastic spontaneous strain is shown to result from the appropriate summation of pure shear strains produced by these soft modes and characterised by a two-dimensional acoustic strain tensor which is proportional to the difference between the spontaneous strain tensors of two strain-compatible ferroelastic orientation states. (24 refs.)

72102 Short-range-order parameters for a binary alloy on the FCC lattice. S.McKenzie (Dept. of Chem., Royal Holloway Coll., Univ. of London, Egham Hill, England).
J. Phys. C (GB), vol.16, no.13, p.2509-15 (10 May 1983).
Short-range-order parameters are calculated for a binary alloy of composition AB on the face-centred cubic lattice. Monte Carlo simulation techniques are used to obtain estimates for these parameters for the first ten coordination shells. The results are compared with those predicted by other approaches and excellent agreement is obtained with series predictions for the Ising ferromagnet. (15 refs.)

72103 Effect of uniaxial compression on the ferroelastic phase transitions in layered $KSc(MoO_4)_2$. L.N.Pelikh (Physicotech. Inst. of Low Temperatures, Acad. of Sci., Kharkov, Ukrainian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1782-3 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3145-7 (Oct. 1982). [received: April 1983]
The author reports the results of a study of the effect of uniaxial compression of the $KSc(MoO_4)_2$ crystal on the temperature of the ferroelastic phase transitions. The $KSc(MoO_4)_2$ crystals were grown by the method of spontaneous crystallization from a molten solution of $K_2Mo_2O_7$. The transition to the ferrophase was detected from the anomalies in the dielectric constant ϵ. The measuring electric field (1000 Hz) and the pressure P were applied parallel to the C_3 axis, perpendicular to the layers. (8 refs.)

72104 A new molecular dynamics method for the study of crystal structure transformations. M.Parrinello (Istituto di Fisica Teorica, Trieste, Italy), A.Rahman.
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.97-109
Recent developments in the theory of molecular dynamics have allowed the modeling on the computer of solid to solid phase transitions. A review of this theory is given, and its applications to a variety of physical systems are briefly described. (17 refs.)

64.70M Transitions in liquid crystals

72105 I-N-A phase diagrams of liquid crystals. Shu Chang-qing, Lin Lei (Inst. of Phys., Acad. Sinica, Beijing, China), Wang Liang-yu.
Commun. Theor. Phys. (China), vol.1, no.1, p.107-10 (1982).
The isotropic liquid (I) ⊥ nematic (N) ⊥ smectic a(a) phase diagrams of homologous series of liquid crystals obtained experimentally may be divided into at least 4 types: (a) bia-(4′-n-alkanote benzal)-1.4 phenylenediamines, (b) 4-n-alkyloxybenzoic acid-4′-n-alkyloxylphenyl ester, (c) 4-n-alkyloxybenzylidene-4′ amino-α-cyano-2 methylbutyl cinnamate, (d) 4-n-alkyloxy-4′-cyanobiphenyl. The authors propose theoretical explanations of the phase diagrams by use of a modified McMillan Hamiltonian. (8 refs.)

72106 Reentrant behavior and cyano substituted aryl p-alkoxycinnamates. N.H.Tinh (Centre de Recherche Paul Pascal, Domaine Univ., Talence, France).
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.285-94 (1983).
Several new homologous series of cyano substituted aryl *p*-alkoxycinnamates have been synthesized. The reentrant behavior of these series is compared with those of the *p*-alkoxybenzoates series. The influence of the length of the conjugated system on the reentrant phenomenon is studied. (25 refs.)

72107 **Calorimetric study of the smectic-*A*-smectic-*C* phase transition in liquid crystals.** M.Meichle, C.W.Garland (Dept. of Chem., MIT, Cambridge, MA, USA).
Phys. Rev. A (USA), vol.27, no.5, p.2624-31 (May 1983).
High-resolution AC calorimetric measurements have been made on azoxy-4,4′-di-undecyl-α-methylcinnamate (AMC-11), butyloxybenzylidene heptylaniline (4O.7), heptyloxybenzylidene hexylaniline (7O.6), and heptyloxybenzylidene butylaniline (7O.4). The heat capacity C_p exhibits a sharp, asymmetric peak near the second-order smectic-*A*-smectic-*C* transition. The C_p values increase in the smectic-*C* phase as the transition temperature T_c is approached and then decrease abruptly at T_c. These data are well described by a mean-field Landau model and are not consistent with the heliumlike critical behaviour expected from the de Gennes model. It is also shown that it is very difficult to distinguish between meanfield and *XY* critical behavior on the basis of data obtained only in the smectic-*C* phase. (18 refs.)

72108 **Heat-capacity study of phase transitions in the liquid-crystal racemic 4-(2′-methylbutyl)phenyl-4′-*n*-nonyloxybiphenyl-4-carboxylate (2M4P9OBC).** J.M.Viner, C.C.Huang (School of Phys. & Astron., Univ. of Minnesota, Minneapolis, MN, USA).
Phys. Rev. A (USA), vol.27, no.5, p.2763-6 (May 1983).
The heat capacity of racemic 4-(2′-methylbutyl)phenyl-4′-*n*-nonyloxybiphenyl-4-carboxylate (2M4P9OBC) has been measured in the vicinity of the Sm*C*-Sm*I*, Sm*I*-Sm*G*, and Sm*G*-Sm*H* phase transitions. The nature of the Sm*C*-Sm*I* transition will be discussed in the context of known microscopic pictures of each phase. In contrast to the continuous Sm*A*-hexatic-*B* phase transition found in *n*-hexyl-4′-*n*-pentyloxybiphenyl-4-carboxylate, an asymmetric heat-capacity anomal is identified in the Sm*C*-Sm*I* transition of 2M4P9OBC. (16 refs.)

72109 **X-ray study of the smectic A-nematic phase transition in 4-n-pentylphenyl-4-(trans-4′-n-pentylcyclohexyl) benzoate.** A.Rajewska, B.Pura, J.Przedmojski (Inst. of Phys., Warsaw Tech. Univ., Warsaw, Poland), R.Dabrowski.
Phys. Status Solidi a (Germany), vol.76, no.1, p.127-30 (16 March 1983).
X-ray critical scattering from $C_{29}H_{40}O_2$ near the smectic A-nematic phase transition are investigated. The critical exponents $\gamma, \nu_\parallel$ and $\nu_\perp$ are extracted from the data. The ratio of the longitudinal to the transverse correlation lengths $\xi_\parallel/\xi_\perp$, increases gradually with decreasing reduced temperature $t=(T-T_c)/T_c$, for $4\times10^{-4}\leq t\leq10^{-3}$. 64.70P Glass transitions

72110 **Effect of DMF on the glass transition temperature of vinylidene chloride-acrylonitrile copolymers.** M.Mucha, M.Kryszewski, A.Stodolny (Tech. Univ., Lodz, Poland).
Plaste & Kautsch. (Germany), vol.30, no.3, p.144-9 (March 1983). In German.
The variation of the glass transition temperature T_G with respect to the thermal expansion coefficients α_L and α_G of different compositions of vinylidene chloride/acrylonitrile copolymers were examined as a function of dimethyl formamide content. Dilatometer measurements show that the T_G value does not follow the known equation for T_G depression of plastics. The solvent appears to have two roles: (1) to reduce segment rotation and sometimes translation by penetrating between the polymer chains; (2) to vary cohesion between polymer chains through strong intermolecular polymer/solvent exchange. (20 refs.) *A.E.W.*

72111 **Influence of free volume fraction, inter/intramolecular energy ratio, and chain segment density on the Gibbs-DiMarzio theory of the glass transition.** A.R.Greenberg, R.P.Kusy (Dental Res. Center, Univ. of North Carolina, Chapel Hill, NC, USA).
Polymer (GB), vol.24, no.5, p.513-18 (May 1983).
Based upon computer analysis, the Gibbs-DiMarzio (G-DM) theory (1958) is evaluated for the case of (a) constant V_0 and (b) constant r where V_0 is the fractional free volume at T_g and r is the ratio of the hole (E_0) to the flex (ϵ) energy. For each respective case, results are presented in a reduced variables format that indicate the extent to which r and V_0 vary at the transition temperature as a function of the reciprocal degree of polymerization (P^{-1}). To further account for chemical differences that exist among polymers, an index (n) is introduced that ultimately incorporates the effective number average of chain atom segments ($\bar{x}$) per P. Using these reduced variables plots, the effects of V_0, r and n are compared with the T_g data for four well-documented polymers. Although the theory adequately describes the PMMA, PS and PVC data, for PαMS the fit is doubtful. The analysis demonstrates that, in order to maintain V_0 within the range of 0.015-0.045, r must remain within approximately 1.0-1.1. Moreover, under conditions of either constant V_0 or r, other more flexible polymers require that $n\gtrsim10$. (49 refs.)

72112 **The thermodynamics of the glass transition.** M.Hillert (Div. of Phys. Metall., Royal Inst. Technol., Stockholm, Sweden).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.3-13
The kinetic theory of the glass transition is examined. Some modifications are suggested in order to overcome some shortcomings. As a result, a thermodynamic description of the glass transition is obtained. It is demonstrated that the glass transition represents the beginning of a very gradual process of melting in the amorphous state. (17 refs.)

64.75 SOLUBILITY, SEGREGATION, AND MIXING

72113 **Solid solution of TiO_2 in mullite.** C.Baudin, M.I.Osendi, J.S.Moya (Inst. de Ceramica y Vidrio, CSIC, Madrid, Spain).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.185-7 (May 1983).
The titania solid solubility limit in mullite has been determined by X-ray diffraction and by X-ray dispersive energy techniques. The close agreement between the results obtained by the two different techniques allows the authors to fix at 1600°C the solid solubility of TiO_2 in mullite at 2.9±0.2 wt.%. (9 refs.)

72114 **Some further factors affecting the solubility of silicate cements [for dentistry].** A.T.Kuhn, W.Lesan, D.Setchell (Bio-Materials Sci. Dept., Inst. of Dental Surgery, London, England).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.191-4 (May 1983).
The authors have explored a number of variables, and show the importance of these on the rate of the dissolution process. These include the total volume of water (eluent) used, the concentration of an ion (F^-) present in the cement and known to be released from it. In addition, the effect of sample geometry has been studied by extending the surface area:volume ratios reported by previous workers. (6 refs.)

72115 **On the temperature of phase dissolution in real crystals.** J.N.Jagodzinski, Y.V.Kornyushin (Inst. of Metal Phys., Acad. of Sci., Kiev, Ukrainian SSR).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.213-14 (May 1983).
The atomic concentration of impurity in the matrix may differ from that averaged over the sample, concentration, in real crystals containing grain boundaries, dislocations, stacking faults and other sinks of impurity atoms. When the impurity content is rather small, this difference is critical. In this case, depletion of impurity in the matrix leads to a decrease of the temperature of the dissolution of the phase. Formulae for the dissolution temperature in real crystals of such systems are obtained and a method of experimental evaluation of the parameters of sinks in interstitial alloys is proposed. (4 refs.)

72116 **The release of organic species from the glass-ionomer cements [for dentistry].** A.T.Kuhn (Bio-Materials Sci. Dept., Inst. of Dental Surgery, London, England), W.A.Lesan, H.A.Painter.
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.224-8 (May 1983).
Eluates of glass-ionomer cements were examined for total organic content and organic release during dissolution. Comparisons were made with studies on silicate cements. The levels of leach-out were found to be reassuringly low. (13 refs.)

72117 **Interaction of impurities with grain boundaries in austenite.** G.A.Filippov (Inst. of Metallography & Phys. of Metals, Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.528-32 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the tendency for segregation of phosphorus, antimony, and tin at the boundaries of the original austenite grains. The strongest tendency was observed for phosporus; antimony and tin were less likely to segregate. Estimates were obtained of the energy of the interaction of phosphorus, antimony, and tin atoms with austenite grain boundaries. It was found that alloying of iron with nickel should increase the energy of the interaction of these impurities with the grain boundaries. (10 refs.) *A.T.*

72118 **A mass spectrometric investigation of the iron-chromium-cobalt system.** B.B.Argent, M.Ellis (Dept. of Metall., Univ. of Sheffield, Sheffield, England), G.Effenberg.
High Temp.-High Pressures (GB), vol.14, no.4, p.409-16 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
Activity measurements have been made with a Knudsen-cell mass spectrometer on Co-Cr and Co-Cr-Fe alloys over the temperature range 1350-2000K. The excess free enthalpies of mixing for liquid and face-centred cubic ternary solutions are negative, but positive values are noted for body-centred cubic solutions. (8 refs.)

72119 **Precipitation as the phenomenon responsible for the electrically inactive arsenic in silicon.** D.Nobili, A.Carabelas, G.Celotti, S.Solmi (CNR, Istituto LAMEL, Bologna, Italy).
J. Electrochem. Soc. (USA), vol.130, no.4, p.922-8 (April 1983).
The physical nature of the electrically inactive arsenic in silicon was investigated by annealing experiments performed on specimens doped in a wide range of concentration, up to 4×10^{21} cm^{-3}, obtained by ion implantation and laser annealing. Thermal treatments of these alloys at temperatures of 800°, 900°, and 1000°C provided solid solubility values which correspond to the carrier density in equilibrium with excess dopant. Additional confirmation that the electrically inactive arsenic is a precipitated phase was obtained by the kinetics of the annealing process. The occurrence of precipitation in an amount which is consistent with that of the electrically inactive dopant was confirmed by small angle X-ray scattering which provided also details on the size and shape of the particles. The latter are in form of thin platelets and match the structure of the silicon lattice. These results clearly contradict the models developed to account for the difference between carrier and arsenic concentration which hypothesize the formation of a high equilibrium concentration of complex point defects making the excess dopant electrically inactive. (31 refs.)

72120 **Clustering and phase separation in a binary alloy on the FCC lattice.** S.McKenzie (Dept. of Chem., Royal Holloway Coll., Univ. of London, Egham Hill, England).
J. Phys. C (GB), vol.16, no.13, p.2517-28 (10 May 1983).
Monte Carlo simulation techniques are used to investigate clustering and phase separation in a binary alloy of equimolar composition (AB) on a face-centred cubic lattice with 6912 sites. The formation of spanning paths and connected clusters of B atoms is studied as a function of the reduced inverse temperature $x(=\Delta\epsilon/kT)$, where $\Delta\epsilon$ measures the difference in the interaction energy between unlike and like nearest-neighbour (NN) pairs of atoms. A further generalisation is introduced into the model in the form of a minimum-valence restriction, so only those B atoms surrounded by at least mNNB atoms are considered in the analysis. Values of m in the range 0 to 10 are treated. (36 refs.)

72121 A statistical mechanical model for chemical disorder in interacting systems: Application to phase separation in alkali silicates, alkaline earth silicates and alkaline earth aluminosilicates. R.J.Araujo (Res. & Dev. Labs., Corning Glass Works, Corning, NY, USA).
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.257-67 (May 1983).
The present model provides a formalism for studying the effects of chemical disorder in a system of interacting atoms in which the number of neighbors of each kind of atom need not be the same. When they are the same, this model reduces to the quasi-chemical approximation. It is applied to a model for phase separation in alkali silicates and alkaline earth silicates which involves a mixture of fourfold and sixfold coordinated species. The sixfold coordinated species represents a pseudo-atom comprised of two silicon atoms each bonded to non-bridging oxygen atoms which are strongly associated. A miscibility dome similar to that observed in sodium silicates and barium silicates is predicted. The suppression of phase separation by alumina is predicted. (5 refs.)

72122 Enthalpy of solution of ammonium iodide in water. R.Weintraub, A.Tamir, A.Apelblat (Dept. of Chem. Engng., Ben Gurion Univ. of the Negev, Beer Sheva, Israel).
J. Chem. Thermodyn. (GB), vol.15, no.5, p.403-7 (May 1983).
New molar enthalpies of solutions of NH_4I in water at 298.15K were measured in an LKB calorimeter. So as to prevent decomposition of ammonium iodide, hydroxylamine sulfate and sodium hydroxide were added in different quantities. The molar enthalpies of solution extrapolated to infinite dilution are: $(13877 \pm 37)\ J.mol^{-1}$ and $(13871 \pm 41)\ J.mol^{-1}$. In the absence of hydroxylamine sulfate and sodium hydroxide, values of $(13940 \pm 35)\ J.mol^{-1}$ (Alfa) and $(13983 \pm 12)\ J.mol^{-1}$ (Merck) were obtained. (8 refs.)

72123 Semiempirical theory of solid solubility in metallic alloys. J.M.Lopez, J.A.Alonso (Dept. de Fisica Teorica, Univ. de Valladolid, Valladolid, Spain).
Phys. Status Solidi a (Germany), vol.76, no.2, p.675-82 (16 April 1983).
A semiempirical theory of solid solubility in metallic alloys is presented. The theory is based on Miedema's semiempirical expression for the heat of solution. Since atomic size mismatch effects are not included in Miedema's theory, and since they are crucial in substitutional solid alloys, a term is added to account for those effects. This term is derived from elastic continuum theory. A simple approximation is used for the entropy of mixing. The theory is applied to continuous solid solutions and to almost insoluble systems. (21 refs.)

72124 Phase separation in epoxy resins containing polyethersulphone. C.B.Bucknall, I.K.Partridge (School of Industrial Sci., Cranfield Inst. of Technol., Cranfield, England).
Polymer (GB), vol.24, no.5, p.639-44 (May 1983).
Scanning electron microscopy and dynamic mechanical spectroscopy have been used to study phase separation of dissolved polyethersulphone (PES) from trifunctional and tetrafunctional epoxy resins during curing. No phase separation was observed at high concentrations of the tetrafunctional resin. Observations of nodules on fracture surfaces, and of multiple peaks in the dynamic mechanical spectra provided evidence for a separate, crosslinked, PES-rich phase in the remaining materials. Despite the variety of morphologies obtained in mixtures of PES with different hardeners and resins, modulus and fracture toughness showed little dependence upon composition. (13 refs.)

72125 Some aspects of the miscibility behavior of polyester/halogenated polymer blends. R.E.Prud'homme (Dept. de Chimie, Univ. Laval, Quebec City, Quebec, Canada).
Polym. Eng. & Sci. (USA), vol.22, no.17, p.1138-42 (mid-Dec. 1982). (Second Mini-Symposium on Polymer Blends, 'Polyblends '82', Montreal, Canada, 20 April 1982).
Glass transition temperature and depression in melting point methods are commonly used to determine the miscibility behavior of polymer/polymer blends, where at least one component of the mixture is semicrystalline. However, these methods often lead to ambiguous and even contradictory results, as is shown by several examples. A comparison of the miscibility behavior of poly(vinyl chloride), poly(vinyl bromide), and poly(vinyl fluoride) with linear and branched polyesters indicates that small changes in the structure of the halogenated polymer and/or of the polyester lead to major changes in miscibility, indicating the subtle nature of the miscibility phenomenon and emphasizing difficulties in its control. (17 refs.)

72126 Sulphur effect on the oxygen induced segregation phenomena on Ni-30%Cr alloy. P.Humbert, A.Mosser (Lab. de Cristallographie, Univ. Louis Pasteur, Strasbourg, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.708-13 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Segregation phenomena induced by oxygen on a (111) face of a nickel-chromium alloy (30%Cr) during oxidation and following vacuum annealing have been studied by Auger electron spectroscopy. Both with a clean and with a sulphur-covered surface, the results show a chromium enrichment provided the temperature allows sufficient mobility of surface atoms. Sulphur enhances this segregation. (12 refs.)

72127 Volumes of mixing of liquid alloys. K.Okajima, H.Sakao (Dept. of Metall., Nagoya Univ., Nagoya, Japan).
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.223-35 (April 1983).
Statistical approach was made with a purpose of explaining the base curves drawn empirically in the cases of excess molar volumes of the liquid Bi-Ag and Bi-Cd alloys measured previously, taking into account number of the valence electrons per atom in the liquid alloys. Thus, the complicated anomalous behaviors in the excess molar volumes with composition were commonly interpreted for a number of the alloy systems. It was made clear that the excess molar volumes deviated from the base curves showed anomalous increase or decrease asymmetrically on both component rich sides, but such behaviors were closely related with the particular compositions in the phase diagrams such as the eutectic, solid solubility limit, intermetallic compound and so on. (62 refs.)

72128 Ostwald ripening in two phase mixtures with application to rapid solidification. P.W.Voorhees, M.E.Glicksman (Materials Engng. Dept., Rensselaer Polytech. Inst., Troy, NY, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.33-47
Rapid solidification invariably results in fine-scale microstructures with concomitant fine-scale segregation. These microstructures, which are produced relatively far from equilibrium, have large specific surface energies and tend to coarsen rapidly. Experiments were carried out on highly supercooled bulk specimens of elemental P_4 in which the average temperature of rapidly solidified 2-phase mixtures was accurately monitored over time. A continuous rise in temperature toward the bulk melting point is always measured, independent of the volume fraction of solid produced at recalescence. New theoretical work shows that this temperature rise can be associated with the Ostwald ripening of the as-solidified solid-plus-liquid mixture. The theory permits calculation of coarsening rates after recalescence and the distribution of dendritic particle sizes as a function of time. Implications for establishing limiting dendritic particle sizes are discussed. (13 refs.)

64.80 OTHER PHASE PROPERTIES OF SYSTEMS

72129 Analysis of mercury cadmium telluride by energy dispersive analysis. D.C.Gillies (Univ. Space Res. Assoc., Marshall Space Flight Center, Huntsville, AL, USA).
J. Electron. Mater. (USA), vol.11, no.4, p.689-97 (July 1982). [received: Nov. 1982]
An electron microprobe analysis technique using energy dispersive spectrometry has been developed for rapid quantitative analysis of mercury cadmium telluride at high spatial resolution. The results can demonstrate a difference of x in $Hg_{1-x}Cd_xTe$ of 0.002 between two locations as close as 5 μm, the accuracy in x being dependent on how well determined are the composition of the standards employed. Damage to the sample is limited by the low (10 keV) excitation potential and low current used. The method is applicable to bulk crystals and LEP grown material. (10 refs.)

72130 Ultrahigh-resolution electron microscopy of charge-density waves in $2H$-$TaSe_2$ below 100K. J.M.Gibson, C.H.Chen, M.L.McDonald (Bell Labs., Murray Hill, NJ, USA).
Phys. Rev. Lett. (USA), vol.50, no.18, p.1403-6 (2 May 1983).
Ultrahigh-resolution transmission-electron micrographs display $3a_0$ periodic distortions of the crystal lattice in $2H$-$TaSe_2$ associated with charge-density waves below 120K. Approximate structure-factor magnitudes and signs within single domains of the commensurate phase are determined. The data fit well only one of the models recently derived from ^{77}Se NMR. The charge-density-wave amplitude is 30% less in the orthorhombic direction for this

model. The center of symmetry within the orthorhombic unit cell is determined. Images from incommensurate phases are discussed. (12 refs.)

72131 Influence of solidification parameters on the microstructure of rapidly quenched Fe-Ni-B alloys. U.Koster (Abt. Chemietech., Univ. of Dortmund, Dortmund, Germany), U.Herold, D.Krause.
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.179-84
The microstructure of Fe-Ni-B alloys rapidly quenched by melt spinning has been investigated by means of light and electron microscopy. Depending on the surface velocity of the quenching wheel and the boron concentration, a large variety of microstructures has been observed: increased solubility of boron, microstructures with different metastable crystalline compounds or metallic glasses. Plotting the as-cast microstructures versus the quenching rate has been found to be very useful for arranging the large amount of results and/or for predicting particular microstructures. Due to an extremely large gradient in the microstructure across the ribbon thickness this method of forming particular microstructures seems to be only of limited advantage. Controlled crystallization reactions of metallic glasses result in different, but more homogeneous microstructures. (7 refs.)

72132 Evaluation of the intermolecular specific heat of quasi-spherical molecular liquids from thermo-acoustic data. B.K.Sharma (Dept. of Phys., Regional Coll. of Education, Bhubaneswar, India).
Phys. Lett. A (Netherlands), vol.95A, no.2, p.107-10 (18 April 1983).
A relationship between the microscopic Gruneisen parameter and the thermodynamic Gruneisen parameter has been examined and analysed for several quasi-spherical molecular liquids and their ratio is utilized to measure the intermolecular specific heat and specific heat ratio. Calculated data on the Gruneisen parameter, intermolecular specific heat ratio and intermolecular isobaric specific heat taken up by the molecular vibrations for these liquids are presented. It is seen that the intermolecular vibrations contribute from about 28 to 50% of the total isobaric specific heat in these liquids. (12 refs.)

65.40 HEAT CAPACITIES OF SOLIDS

(for specific heat of superconductors, see 74.30E; for specific heat of magnetic systems, see 75.40)

72133 Thermophysical properties of the intermetallic Mn_3MN perovskites. I. Heat capacity of the manganese nitride Mn_4N. J.Garcia, J.Bartolome, D.Gonzalez (Dept. de Termologia, Univ. of Zaragoza, Zaragoza, Spain), R.Navarro, D.Fruchart.
J. Chem. Thermodyn. (GB), vol.15, no.5, p.465-73 (May 1983).
The heat capacity of Mn_4N has been determined in the range from 5 to 345K by adiabatic calorimetry and between 335 and 500K using DSC. No anomaly was found in the temperature range covered. The thermodynamic functions at 298.15K are $C_p/R=15.01$, $S°(T)/R=17.19$, $\{H°(T)-H°(0)\}/R=2712.8$K, and $\{G°(T)-H°(0)\}/RT=8.089$. From the analysis of the various contributions to the heat capacity, the values $\gamma=0.042$ $J.mol^{-1}.K^{-2}$ for the electronic coefficient, and $\Theta_D(0)=433$K for the Debye temperature at $T\rightarrow 0$, have been obtained. The determination of the lattice contribution for $T<350$K will allow one to use it as a common lattice base line to estimate the lattice contribution to C_p of other members of the series. (19 refs.)

72134 Specific heat of lead chalcogenides. S.N.Lykov, I.A.Chernik (Kalinin Polytech. Inst., Leningrad, USSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1755-7 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3102-5 (Oct. 1982). [received: April 1983]
A comparative study of the lattice specific heat C_p of lead chalcogenides has been carried out at temperatures in the hydrogen-helium range. The behavior of $C_p(T)$ in this range of PbSe and PbS was investigated first. Under the traditional interpretation of the measurements in terms of the Debye theory the authors obtained the temperature dependence of $\theta_D(T)$, demonstrating the qualitative and quantitative agreement of the phonon spectra of these compounds. For the limiting magnitudes of $\theta_D(0)$ they have found the values 170, 200, and 210K for PbTe, PbSe, and PbS, respectively. They have also observed, and discuss briefly, a number of anomalies in the specific heat of these materials. (5 refs.)

72135 Thermodynamic properties of impurity band electrons. S.D.Baranovskii, A.A.Uzakov, A.L.Efros (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.422-9 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.756-67 (Aug. 1982). [received: May 1983]
The electronic specific heat $c_v(T)$ of a lightly doped compensated semiconductor is computed in a broad range of temperatures with the aid of the method of Monte Carlo computer simulation of the impurity band. The results of the simulation of the three-dimensional system confirm the existence in the function c_v/T of the low-temperature dip that was predicted earlier on the basis of a self-consistent equation for the density of dipole-excitation states. Somewhat unexpected is the discovery of a similar dip in the case of the two-dimensional system, for which the self-consistent-equation method does not reveal any low-energy anomalies in the density of states of the excitations determining the specific heat. New data pertaining to the properties of the ground state of the system in question are obtained incidentally. (9 refs.)

65.50 THERMODYNAMIC PROPERTIES AND ENTROPY

72136 Analytical evaluation of ternary thermodynamics from investigations by Knudsen-cell mass spectrometry. J.Tomiska (Inst. fur Phys. Chem., Univ. Wien, Wien, Austria).
High Temp.-High Pressures (GB), vol.14, no.4, p.417-22 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
The application of Knudsen-cell mass spectrometry to thermodynamic investigations on ternary systems is very limited. The experimental effort required is very large and evaluation of the measured data is very time-consuming. A considerable reduction both of the experimental work and of the time spent on evaluation can be expected by applying the suggested analytical evaluation technique. This is based on an adapted Redlich-Kister approximation of the excess thermodynamic functions which is suitable for computer calculations. The technique is then to adjust the expansion parameters by a best fit of all the experimental data for the entire composition range. Consequently investigations along special concentration lines with a constant ratio of the mole fractions of two components are no longer required and there is therefore a reduction in experimental effort. The suggested evaluation technique is described for applications to investigations by means of the ratio/Gibbs-Duhem method, but is also easily applicable to the evaluation of other mass spectrometric data. (22 refs.)

72137 Thermodynamics of the $U_xPu_{1-x}O_{2-z}$ system in the liquid range. J.-F.Babelot, M.Hoch, R.W.Ohse (Commission of the European Communities Joint Res. Centre, Karlsruhe Establ., European Inst. for Transuranium Elements, Karlsruhe, Germany).
High Temp.-High Pressures (GB), vol.14, no.4, p.431-9 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
To calculate the vapour pressures of the various gaseous species above $U_xPu_{1-x}O_{2-z}$, especially in the liquid range, a regular-solution model has been developed for the mixture UO_2-PuO_2-$PuO_{1.5}$, and the various free energies of formation have been evaluated. In the UO_2-PuO_2-$PuO_{1.5}$ triangle, the UO_2-PuO_2 system is ideal; in the UO_2-$PuO_{1.5}$ system the interaction parameter is 5.15 kJ mol^{-1}; and in the PuO_2-$PuO_{1.5}$ system the interaction parameter is 15.14 kJ mol^{-1}. The free energies of formation are summarized, and an example of calculation of the partial pressures is shown. (21 refs.)

72138 Thermodynamic evaluation of mixed working fluids. Y.Yoshida, Y.Mukai (Central Res. Lab., Matsushita Electric Industrial Co. Ltd., Osaka, Japan).
Natl. Tech. Rep. (Japan), vol.29, no.1, p.111-19 (Feb. 1983). In Japanese.
Mixed working fluids have recently attracted attention, especially in refrigeration cycle, Rankine cycle, and thermosyphon cycle, but there is little information on their thermodynamic properties. Consequently the authors have developed estimation programs by using a generalized equation of state, applying new methods in evaluating enthalpy and entropy of the vapor-liquid coexisting phase. They have also examined programs for mixtures of fluorinated hydrocarbons, and provided techniques which give more precise estimation. Finally, they have completed an automatic plotting system of characteristic diagrams such as the VLE diagram, pressure-enthalpy diagram, temperature-entropy diagram and enthalpy-composition diagram. 65.70 THERMAL EXPANSION AND THERMOMECHANICAL EFFECTS

(see also 64.30 Equations of state; for electronic thermal conduction, see 72.15 and 72.20; for thermal conductivity of superconductors, see 74.30E; for pyroelectric and electrocaloric effects, see 77.70)

72139 Effect of pressure on the measurement of thermal expansion of polymers. T.I.Ponomareva, Yu.M.Paramonov, V.I.Irzhak, B.A.Rozenberg.
Vysokomol. Soedin. Ser. B (USSR), vol.25, no.3, p.205-6 (1983). In Russian.
The value of the thermal expansion coefficient in viscoelastic polymers depends on measuring conditions, and chiefly on applied stress. Experimental results are therefore often not reproducible. Here the thermal expansions of epoxy polymers are reported as functions of applied pressure. It is shown that in the vitreous state the thermal expansion coefficient is dependent of stress, but that it increases linearly with applied stress for viscoelastic polymers. (3 refs.) *C.J.S.*

72140 Generation of thermal strains in GRP. I. Effect of water on the expansion behaviour of unidirectional glass fibre-reinforced laminates. F.R.Jones, M.Mulheron, J.E.Bailey (Dept. of Metall. & Materials Technol., Univ. of Surrey, Guildford, England).
J. Mater. Sci. (GB), vol.18, no.5, p.1522-32 (May 1983).
The temperature dependence of the linear expansion coefficients in the longitudinal (α_l) and transverse directions ($\alpha_{t(1)}$ and $\alpha_{t(2)}$) of unidirectional glass fibre laminates and their matrix resins (α_m) has been studied. The results for the dry, fully post-cured polyester, epoxy resins and laminates have been found to be consistent with the predictions of the Schapery equations. An anomalous moisture phenomenon, in the form of a peak in the $\alpha_m(T)/T$ and $\alpha_t(T)/T$ curves for the polyester resin and laminates has been observed. A difference between $\alpha_{t(1)}$ and $\alpha_{t(2)}$ has been observed for partially cured polyester laminates, which is also perturbated in the presence of water. Both these moisture effects, which are not found in the epoxy specimens, are considered to result from a two-phase polyester matrix and the latter to continued curing below the softening point of the resin. These results have a considerable consequence on the magnitude of the thermal strains which develop in polyester composites. (19 refs.)

72141 Generation of thermal strains in GRP. II. The origin of thermal strains in polyester cross-ply laminates. F.R.Jones, M.Mulheron, J.E.Bailey (Dept. of Metall. & Materials Technol., Univ. of Surrey, Guildford, England).
J. Mater. Sci. (GB), vol.18, no.5, p.1533-9 (May 1983).
For pt.I see ibid., vol.18, p.1522-32 (1983). The temperature dependence of the thermal strains in the longitudinal direction of the transverse ply $\epsilon_{tl}{}^{th}$, of 0°/90°/0° epoxy and polyester laminates, has been determined from the thermal variation of the deflection of an unbalanced beam. These results have been compared with those predicted from known values of the linear expansion coefficients α_t and α_l. There is good agreement between the experimental and calculated values of thermal strain for the epoxy composite. Good agreement for the polyester laminates can only be obtained when the values of α_t used are those for wet laminates. The large thermal strains previously reported for the polyester laminates can therefore be explained by small quantities of water in the matrix which are not readily removed during post-curing. (12 refs.)

72142 Study of the swelling of an Al-Ar-O alloy by an acoustic emission method. M.E.Gurevich, V.S.Zgura, L.N.Larikov (Inst. of Metal Phys., Acad. of Sci., Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.731-3 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.57-9 (Sept. 1982). [received: March 1983]
The material investigated was a metastable aluminum-argon-oxygen alloy containing fine alumina particles. A single physical (acoustic emission) method was employed for studying the swelling dynamics of this material. Stress waves set up by swelling processes were recorded by means of a piezoelectric pickup and apparatus including standard units for studying acoustic emission signals. Measurements were made under conditions of continuous heating at a rate of 10K/min. A characteristic spectrum of acoustic emission of the Al-Ar-O alloy during heating is shown. It reveals four clearly defined swelling stages, each being represented by a surge of acoustic signal intensity. (3 refs.)

65.90 OTHER TOPICS IN THERMAL PROPERTIES OF CONDENSED MATTER

72143 IR emission spectroscopy of molten salts and other liquids using thick samples as reference. J.Hvistendahl, E.Rytter, H.A.Oye (Inst. of Inorganic Chem., Norwegian Inst. of Technol., Univ. of Trondheim, Trondheim, Norway).
Appl. Spectrosc. (USA), vol.37, no.2, p.182-7 (March-April 1983).
The IR emittance of liquids relative to a blackbody is dependent on the reflectivity at the surface of the sample. This dependency leads to distortions in the bandshapes except when the absorption coefficient or the sample thickness is very low. The use of an opaque (i.e. very thick) samples as a reference eliminates the distortions in the bandshapes. A new emittance ϵ^*=(emission of a thin sample)/(emission of an opaque sample) has been introduced. A theoretical analysis as well as experimental work on chloroaluminate melts demonstrate that the emittance ϵ^* gives a better representation of the ideal sample property of interest, i.e. the internal transmittance of the sample, than does the usual emittance with a blackbody as a reference. (19 refs.)

72144 Integral emittance of niobium during high-temperature heating and oxidation. V.K.Mel'nikov, V.N.Kovalev.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.69-74 (1983). In Russian.
Results of an experimental investigation of chemical kinetics and integral normal emittance of chemically-reacting niobium plates during non-stationary heating by a high-temperature argon-oxygen flow are presented. (8 refs.)

66.00 TRANSPORT PROPERTIES OF CONDENSED MATTER (NONELECTRONIC)

66.10 DIFFUSION AND IONIC CONDUCTION IN LIQUIDS

72145 The determination of ionic transport numbers by use of radiotracers. P.J.Smith, T.L.Jones (Winnington Lab., ICL pcl, Winnington, Northwich, England).
J. Electrochem. Soc. (USA), vol.130, no.4, p.885-90 (April 1983).
Reports details of a recirculating transport cell for the determination of sodium ion transport numbers by radioactive tracer methods. The construction and operation of the transport cell are discussed and, in order to illustrate the scope of the transport cell, data concerning sodium ion transport in a 1200 equivalent weight Nafion membrane are presented. The ion transport data are interpreted in terms of membrane electrolyte sorption and membrane water content. (9 refs.)

72146 Radiometric absorption method for continuous observation of diffusion in molten metals. P.Kubicek, B.Vozniakova (CSAV, Ostrava, Czechoslovakia).
Jad. Energ. (Czechoslovakia), vol.29, no.4, p.136-41 (April 1983). In Czech.
The radiometric absorption method for continuous observation of diffusion in molten metals is analysed. On the basis of its theory experimental equipment was assembled and measurements of ^{110}Ag diffusion into molten Zn at a temperature near the boiling point of Zn was carried out. The values of the diffusion coefficient of ^{110}ag→Zn at the mean temperature 886.5°C ranged from $(7\text{-}10)\times10^{-5}$ cm^2/s. (7 refs.)

72147 Self and mutual diffusion measurements in dilute and semidilute polystyrene solutions. T.Cosgrove, J.M.Sutherland (School of Chem., Univ. of Bristol, Bristol, England).
Polymer (GB), vol.24, no.5, p.534-6 (May 1983).
Self-diffusion coefficients have been obtained for polystyrene (M_w=37000) solutions in toluene (D_8) and cyclohexane (D_{12}) by the pulsed field gradient NMR technique at 303K. Mutual diffusion coefficients have been obtained by photon correlation spectroscopy (PCS). In a poor solvent (cyclohexane) both techniques show a similar trend of a monotonic decrease in the diffusion coefficient with increasing concentration of polymer. However, in a good solvent (toluene) NMR shows a monotonic decrease in the diffusion coefficient whereas PCS shows an increase. The results are discussed in terms of self and mutual diffusion processes. (17 refs.)

66.20 DIFFUSIVE MOMENTUM TRANSPORT

(inc. viscosity of liquids)

72148 The temperature dependence of coefficient of viscosity for $Cu_{60}Zr_{40}$ and $Ni_{64}Zr_{36}$ metallic glasses. E.Girt (Faculty of Sci., Univ. of Sarajevo, Sarajevo, Yugoslavia).
Fizika (Yugoslavia), vol.15, no.1, p.29-35 (Jan.-March 1983).
The cold finger method was used for dilatometric measurements of $Cu_{60}Zr_{40}$ and $Ni_{64}Zr_{36}$ amorphous samples at elevated temperatures under applied tensile stress. The creep process was identified from the experimental data by separation of the free volume annealing process. It was found out that this process occurs at lower temperatures for the $Ni_{64}Zr_{36}$ system and that it follows a linear time dependence. The coefficient of viscosity was evaluated from the data for creep for both systems, their functional dependence on temperature was given and activation energies for the systems were evaluated. The obtained temperature dependence of the coefficient of viscosity was of the form $\eta=\eta_0\exp(\Delta E/kT)$. The evaluated activation energies for $Cu_{60}Zr_{40}$ and $Ni_{64}Zr_{36}$ amorphous systems were 178.8 kJ/mole and 41.2 kJ/mole, respectively. (6 refs.)

66.30D Theory of diffusion and ionic conduction in solids

72149 Theory of diffusion in a polycrystalline materials. G.Zaeschmar (Energy Conversion Branch, Naval Ocean Systems Center, San Diego, CA, USA).
J. Appl. Phys. (USA), vol.54, no.5, p.2281-6 (May 1983).
A new approach to the general theory of diffusion in polycrystalline materials has been taken. By means of introduction of a third empirical parameter, the filling time of a grain, the mass transfer coefficient between the boundary of two media can be determined in only a typical grain dimension and the bulk diffusion constant are known. A subsequent expression for the diffusion in a finite length grain boundary permits the determination of the grain boundary diffusion constant. A stack of circular cylinders is used as a model. It permits calculation of the concentration functions for large penetration depth as well as bottom to top filling of an individual cylinder.

72150 Quantum diffusion of atoms in a crystal. Localization and phonon-stimulated delocalization. Yu.Kagan, L.A.Maksimov (I.V. Kurchatov Inst. of Atomic Energy, Moscow, USSR).
Phys. Lett. A (Netherlands), vol.95A, no.5, p.242-4 (2 May 1983).
Localization phenomena in the subsystem of interacting particles which diffuse by tunneling in a crystal is considered. The temperature dependence of the diffusion coefficient is found for the regime of phonon-stimulated delocalization. The quantum diffusion in ^{3}He-^{4}He solid state solution is analysed especially, and comparison is made with the results of Micheev et al. (1982) who first observed this phenomenon. (10 refs.)

66.30H Self-diffusion and ionic conduction in nonmetals

72151 Self-interstitial and vacancy contributions to silicon self-diffusion determined from the diffusion of gold in silicon. F.Morehead (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA), N.A.Stolwijk, W.Meyberg, U.Gosele.
Appl. Phys. Lett. (USA), vol.42, no.8, p.690-2 (15 April 1983).
The authors present an analysis of gold diffusion profiles in silicon taking into account that both self-interstitials and vacancies are present at thermal equilibrium. They find that at 1000°C the contribution of self-interstitials to silicon self-diffusion is about equal to that of vacancies. (19 refs.)

72152 Sodium deposition in fast ion conductors. Guo Zhu-kun, Li Xiang-ting (Shanghai Inst. of Ceramics, Acad. Sinica, Shanghai, China).
Acta Phys. Sin. (China), vol.32, no.3, p.406-10 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
Sodium deposition in beta-, beta″-Al_2O_3 and Nasicon ($Na_3Zr_2Si_2PO_{12}$) was studied by using EPMA. Based on the mechanism of ion transportation and electrolytic deposition with a diminished carrier concentration, a kinetic equation for sodium deposition has been derived, which can fit well the time dependence of the sodium counts during electron bombardment. Since an abundant source of mobile Na^+ ions exists in the large single crystal, the rise of the curve of beta-Al_2O_3 extends over a long period of time. However, the crystallites in the Nasicon polycrystal are small ($<10\ \mu m$) the Na^+ ion therefore may be provided insufficiently at the electron bombarded point for a prolonged deposition due to the hindrance of the grain boundaries in the ion transport process. The deposition attains its saturation limit rapidly. (10 refs.)

72153 Interface between solid electrode and solid electrolyte—a study of the $Li/LiL(Al_2O_3)$ solid-electrolyte system. T.R.Jow, C.Liang (Electrochem Industries Inc., Clarence, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.737-40 (April 1983).
The interface contact between a solid electrolyte and a solid electrolyte during discharge was examined, using the $Li/LiI(Al_2O_3)/PbI_2$, Pb solid-state galvanic cell. Upon discharge, Li at the interface is oxidized to Li^+ which migrates through the electrolyte to the cathode. The departing Li^+ ions leave vacant sites at the Li anode surface. When the discharge rate exceeds the diffusion rate of Li to fill the vacant sites, the interface contact may be damaged resulting in a separation between the Li anode and the $LiI(Al_2O_3)$ electrolyte. Based on the discharge time required for such a separation to occur, the Li diffusivity in the Li anode was determined to be $(5.6\pm0.9)\times10^{-11}\ cm^2/sec$ at ambient temperature (24°±2°C). In addition, from the results of anode polarization experiments, the exchange current density of $Li/LiI(Al_2O_3)$ was determined to be $145\pm25\ \mu A/cm^2$ at 24°±2°C. (8 refs.)

72154 Optical and electrical properties of yttria stabilized zirconia (YSZ) crystals. R.C.Buchanan, S.Pope (Dept. of Ceramic Engng., Univ. of Illinois at Urbana-Champaign, Urbana, IL, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.962-6 (April 1983).
Optical transmission spectra ($\lambda=0.3$-$50\ \mu m$) and DC conductivity (25°-1000°C) data were obtained on yttria stabilized zirconia (YSZ) single crystals commercially grown by the skull-melting process. The crystals were doped with up to 2.0 w/o rare earth (Ce, Nd, Er, Pr) and transition (Mn, Fe, Cr, Ni) metal ions, and a few were annealed. Dopant effects were most pronounced in the visible region, but were evident throughout much of the spectral range. Annealing and dopant ions Ce and Er showed significant absorption effects attributed to the Ce^+ ion. Electrical conductivity was only marginally affected by doping. (12 refs.)

72155 Ionic conductivity of sodium β'' alumina in the very far infrared. W.Hayes, G.F.Hopper (Clarendon Lab., Oxford Univ., Oxford, England).
J. Phys. C (GB), vol.16, no.13, p.2529-36 (10 May 1983).
The authors have carried out measurements of the ionic conductivity of sodium β'' alumina in the region 2-200 cm^{-1}. The temperature dependence of the measurements was studied in the range 2-600K. The results show many configurations of sodium ions in the conduction slab of sodium β'' alumina and are used to draw comparisons between the conduction mechanisms of sodium β alumina and sodium β'' alumina. (14 refs.)

72156 Electrical behaviour of doped-yttria stabilized zirconia ceramic materials. C.Pascual, J.R.Jurado, P.Duran (Inst. de Ceramica y Vidrio, CSIC, Madrid, Spain).
J. Mater. Sci. (GB), vol.18, no.5, p.1315-22 (May 1983).
Single-phase sintered ceramic materials $(ZrO_2)_{1-x}\{(Y_2O_3)_y(RE_2O_3)_{1-y}\}_x$ (RE=Nd, Ce, Dy, Er) were synthesized and electrical conductivity and transport number measurements were made as a function of temperature between 500 and 1200°C. The activation energies of conduction were determined, and it was found that the charge carriers in these solid solutions are oxygen ions. The fabricated electrolyte discs were used in cells of the type P_{O2}, Pt/zirconia solid solution/P'_{O2}, platinum where P_{O2}=air (0.21 atm) and P'_{O2}=1 atm or argon-O_2 mixtures. Below 700°C, the EMF deviated from the theoretical values for completely ionic conduction; good agreement was observed above this temperature. (17 refs.)

72157 Oxygen self-diffusionin MgO single crystals. Y.Oishi, K.Ando, H.Kurokawa, Y.Hiro (Dept. of Nuclear Engng., Kyushu Univ., Hakozaki, Fukuoka, Japan).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.C60-2 (April 1983).
Oxygen self-diffusion coefficients in two MgO single crystals were determined by an isotope exchange technique at 1300° to 1750°C using chemically polished samples. There is a sharp break in the temperature dependence at 1500°c. The high-temperature regime is represented by $D=6.76\ \exp[-536(kJ/mol)/RT]\ cm^2/s$, indicating an impurity-insensitive diffusion mechanism. Extrinsic diffusion in the low-temperature regime was interpreted to be structure-sensitive. (10 refs.)

72158 Effect of gamma radiation on the direct-current resistivity of GeO_2. R.H.Magruder,III, D.L.Kinser, R.A.Weeks (Coll. of Engng., Vanderbilt Univ., Nashville, TN, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.C62-3 (April 1983).
Results of DC resistivity measurements on high-purity GeO_2 glasses before and after radiation with ^{60}Co are reported. For these glasses, the DC resistivity is increased by irradiation in a stable and reproducible fashion. This effect is attributed to the interaction of radiation-induced defects with the sodium-ion charge carriers. (13 refs.)

72159 Influence of disorder on the diffusion of alkali ions in SiO_2-and GeO_2-glasses. R.Kirchheim (Inst. fur Werkstoffwissenschaften, Max-Planck-Inst. fur Metallforschung, Stuttgart, Germany).
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.243-55 (May 1983).
The frequency factor and activation energy for the diffusion of Na and K in SiO_2-glasses are strongly dependent on the concentration of Na_2O or K_2O respectively. A similar behavior was found for hydrogen diffusion in amorphous metals. In the last case the results are in agreement with theoretical calculations, if a Gaussian distribution of activation energies is assumed which arises from a similar distribution of the potential energy of hydrogen being in equilibrium sites. The equations derived were used in this study to describe the concentration dependence of Na and K diffusion in SiO_2 glasses, because these impurities are dissolved in randomly distributed interstices of different volume as well. The theory yields the two experimental facts that diffusion below the glass transformation temperature is governed by a single activation energy and that concentration profiles of the tracer atoms can be described by a constant diffusion coefficient. A comparison with low temperature results for Na diffusion shows they agree with theoretical predictions and yield the following parameters: most probable value of the activation energy=59.4 kJ/mol, corresponding frequency factor=$2\times10^{-3}\ cm^2/s$ and half width of the Gaussian distribution=25 kJ/mol. The model also predicts a minimum in plots of the chemical diffusivity versus concentration which is in agreement with experimental findings for sodium diffusion in GeO_2. (23 refs.)

72160 Influence of the electric double layer on glass leaching. T.M.Sullivan (Nuclear Engng. Program, Univ. of Illinois, Urbana, IL, USA), A.J.Machiels.
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.269-82 (May 1983).
When a glass comes into contact with water, an electric double layer forms at the glass-water interface. An analytical model that calculates the electric field and the resulting velocity of univalent alkali ions migrating in the glass matrix is developed. The ion migration velocity is calculated for an 85% SiO_2-15% Na_2O glass and for more complex glasses. The calculations indicate that the process of ion migration leads to normalized leach rates which are small compared to glass network dissolution rates. (18 refs.)

72161 Tracer diffusion and electrical conductivity in sodium-cesium silicate glasses. H.Jain, N.L.Peterson, H.L.Downing.
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.283-300 (May 1983).
The tracer diffusion coefficients of ^{22}Na and ^{137}Cs, and the electrical conductivity have been measured in the $(Na, Cs)_2O{:}3SiO_2$ glasses as a function of temperature and Cs/Na ratio. Complex impedance analysis was used for the conductivity measurements. The Haven ratio at 396.5°C increases from 0.3-0.4 in single-alkali glasses to 0.8 for the mixed-alkali compositions. The results are explained in terms of a single-jump mechanism; interactions between alkali ions and non-bridging oxygen ions, and between different alkali ions, produced the observed correlation effects. (26 refs.)

72162 Ionic conductivity of amorphous $mNaF$-nMF_3 thin films ($M=Al$, Cr). J.-M.Dance, T.Oi (Central Res. Lab., Hitachi Ltd., Tokyo, Japan).
Mater. Res. Bull. (USA), vol.18, no.3, p.263-8 (March 1983).
Evaporated 0.5 to 0.7 μm thick thin films of $mNaF$-$nAlF_3$ and $mNaF$-$nCrF_3$ were prepared in a 1 mPa vacuum on glass substrates kept at room temperature. Chemical analysis and AC conductivity measurement revealed that in each case studied, a high ionic conductivity plateau existed for the composition range $0.1<n/(m+n)<0.4$. The maximum conductivities at room temperature were $\sigma=1\times10^{-6}$ S/m for NaF-AlF_3 and $\sigma=2\times10^{-5}$ S/m for NaF-CrF_3. Those high conductivities were discussed in terms of arrangement of MF_6 octahedra. (9 refs.)

72163 Extremely rapid outdiffusion on *n*-type impurities in InP. A.K.Chin, B.V.Camlibel, V.Dutt, V.Swaminathan, W.A.Bonner (Bell Labs., Murray Hill, NJ, USA), A.A.Ballman.
Appl. Phys. Lett. (USA), vol.42, no.10, p.901-3 (15 May 1983).
During sealed ampoule annealing at 550°C, an unexpected, deep diffusion front were determined to be $1\text{-}5\times10^{-8}$ cm^{-8} cm^2 s^{-}1 which is approximately two orders of magnitude greater than that of the rapidly diffusing Zn impurity. By measuring the changes in the CL intensity and the photoluminescence linewidth to determine the changes in carrier concentration, the diffusion fronts were shown to be caused by the outdiffusion of the dopants. Although outdiffusion of Cr and Fe, affecting an ~1 μm surface region during thermal annealing at 550°C for 30 min, has previously been reported observationm of rapid outdiffusionof *n*-type impurities that can affect InP crystals to a substantial depth (~200 μm) for similar annealing conditions. (15 refs.)

72164 Electrical properties of Te diffused silicon. Yong-Hyun Paek, Chul-Sung Kim.
Trans. Korean Inst. Electr. Eng., vol.31, no.12, p.198-205 (1982). In Korean.
The diffusion coefficient of tellurium in silicon is measured. The concentration distribution of tellurium is determined by the method of the sheet resistance and the junction depth through the oxide layer, and by the measurement of the sheet resistance and sheet Hall coefficient as a function of temperature. The temperature dependence of the diffusion coefficient of Te with the energy level of 0.14 ± 0.01 eV below the conduction band edge in silicon can be expressed: $D=1.1\times10^{-2}\exp[-(2.6\pm0.2)\ \mathrm{eV}/kT]\ \mathrm{cm^2/sec}$. (28 refs.)

72165 Influence of material properties on the retention of fission products by silicon carbide coatings. R.Forthmann, E.Gyarmati, J.Linke, E.Wallura (Inst. fur Reaktorwerkstoffe, Kernforschungsanlage Julich GmbH, Julich, Germany).
High Temp.-High Pressures (GB), vol.14, no.4, p.477-85 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
Annealing of cold-irradiated coated fuel particles gave diffusion coefficients of $^{110}\mathrm{Ag}^{m}$ in silicon carbide coatings as a function of the SiC deposition temperature and the carrier-gas composition. The silver diffusion coefficient was found to increase from 8.0×10^{-17} m^2 s^{-1} to 2.0×10^{-16} m^2 s^{-1} with deposition temperatures ranging from 1300 to 1550°C, if SiC was deposited in pure hydrogen. In SiC coatings deposited in argon-hydrogen mixture the silver diffusion coefficients were found to decrease from 9.9×10^{-17} m^2 s^{-1} to 7.3×10^{-17} m^2 s^{-1} over the same range of deposition temperatures. This transport behaviour is not directly correlated with microstructural defects, density, grain size, and optical parameters of the coatings. However, radially oriented regions with different responses to etching seem to play a decisive role in the diffusion of silver in silicon carbide coatings. (5 refs.)

72166 High temperature internal oxidation behaviour of dilute Ni-Al alloys. H.Hindam (Lawrence Berkeley Lab., Univ. of California, Berkeley, CA, USA), D.P.Whittle.
J. Mater. Sci. (GB), vol.18, no.5, p.1389-401 (May 1983).
The internal oxidation of dilute Ni-Al alloys, either pure or containing small additions of tantalum or hafnium, was investigated at 1200°C in air. The advance of the precipitation zone followed la parabolic relationship at a slightly decreasing rate with increasing aluminium content. The precipitate shape, size and spacing depended upon the aluminium concentration and more significantly on the active element additions. The morphology varied from polyhedral crystallites and epitaxial platelets in the Ni-0.5 wt% Al alloy, to well-defined cylindrical rods extending across the precipitation zone approximately normal to the reaction interface, in the alloys of higher aluminium content. An also continuous and similarly oriented plate-like morphology was observed in the active element-containing alloys. X-ray microanalysis indicated that the continuous precipitates consisted of $NiAl_2O_4$ and Al_2O_3. No correlation was found between either the growth rate or oxygen permeability and the distribution of the precipitates. It was, therefore, concluded that the interfacial boundaries were ineffective in accelerating oxygen transport at this elevated temperature. (23 refs.)

72167 Centrifuge studies of the sedimentation of nickel in lead. S.K.Sen, H.B.Huntington (Dept. of Phys., Rensselaer Polytech. Inst., Troy, NY, USA), R.S.Sokolowski.
Scr. Metall. (USA), vol.17, no.4, p.569-72 (April 1983).
The technique of sedimentation under a centrifugal force field is used to study the equilibrium configuration of Ni solute impurities in lead. The mechanism of diffusion is discussed. (13 refs.)

72168 Determination of diffusion coefficients of tritium in the α-phases of titanium and Hafnium. W.Kunz, H.Munzel, U.Helfrich, H.Horneff (Inst. fur Anorganische Chem. & Kernchem., Techn. Hoschschule Darmstadt, Darmstadt, Germany).
Z. Metallkd. (Germany), vol.74, no.5, p.289-93 (May 1983). In German.
Studies on the diffusion of tritium in the IV-b-metals titanium and hafnium were performed. The results are: Ti: $D=2.1\times10^{-3}$ cm^2/s$\times\exp(-46.6$ kJ/mol$/RT)$ $133°\mathrm{C}<T<415°\mathrm{C}$ Hf:$D=6.0\times10^{-4}$ cm^2/s$\times\exp(-41.9$ kJ/mol$/RT)$ $200°\mathrm{C}<T<360°\mathrm{C}$. To implant tritium in the specimens a nuclear-reaction-method was used, allowing a tritium-implantation being independent of the chemical properties of the metal surface. The results are discussed and compared with published data on the ^{1}H-diffusion. (28 refs.)

66.30L Diffusion, migration, and displacement of other defects

72169 Establishment of a relationship between the diffusion parameters and microscopic characteristics of point defects by the computer simulation method. B.F.Kostromin, Yu.M.Plishkin, I.E.Podchinenov, I.Sh.Trakhtenberg (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.450-4 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A method for calculating the diffusion parameters using a dynamic computer model was proposed earlier by the present authors [Fiz. Met. Metalloved. 53, 109 (1982)]. An analysis of the relationship between the activation energy of heterodiffusion and microscopic characteristics of the interaction of point defects is given in the present paper. This makes it possible to select critically the potential of the interaction of the matrix atoms with one another and with impurity atoms and, moreover, it suggests a way of obtaining a microscopic description of diffusion on the basis of the experimental data. Moreover, the microscopic diffusion parameters can be calculated if the energy of the interaction of impurity atoms with vacancies is known. (14 refs.) *A.T.*

72170 Grain-boundary diffusion in metals. N.L.Peterson (Materials Sci. Div., Argonne Nat. Lab., Argonne, IL, USA).
Int. Met. Rev. (GB), vol.28, no.2, p.65-91 (1983).
The available models for grain-boundary diffusion are reviewed together with the relevant mathematical techniques for extracting the grain-boundary diffusivity from the various types of experimental data. The more useful experimental techniques are described, followed by a presentation of results that shed light on the models and mechanisms of grain-boundary diffusion. A 'pipe' mechanism of diffusion based on the well established dislocation model seems most appropriate for small-angle boundaries. Open channels which have atomic configurations somewhat like dislocation cores, probably play a major role in high-angle grain-boundary diffusion. Dissociated dislocations and stacking faults are not efficient paths for grain-boundary diffusion. The diffusion and computer-modelling experiments are consistent with a vacancy mechanism of diffusion by a rather well localized vacancy. The atomic migration is a three-dimensional process with jumps away from, and back towards, the dislocations as well as jumps along the dislocation core. (130 refs.)

66.30N Chemical interdiffusion

72171 Diffusion of toluene in polystyrene and improved free volume theory. A.I.Maklakov, T.A.Serebrennikova.
Vysokomol. Soedin. Ser. B (USSR), vol.25, no.3, p.157-60 (1983). In Russian.
A universal free volume model is proposed for diffusion in polymers, which is valid for self-diffusion and inter-diffusion of macromolecules and small molecules. The improved model is based on the premise that the volume of a body is determined by the sum of its volume at 0K, its continuous free volume as caused by anharmonic molecular vibrations, and the free volume of holes. The model is used to calculate the temperature dependence of the diffusion coefficient for toluene in polystyrene. The calculated values agree closely with literature, experimental data in the range 320-350K. At lower temperature, however, the calculated values are significantly lower. (8 refs.) *C.J.S.*

66.30Q Electromigration

72172 Experimental verification of the space-charge model for electrokinetics in charged microporous membranes. G.B.Westermann-Clark, J.L.Anderson (Dept. of Chem. Engng., Carnegie-Mellon Univ., Pittsburg, PA, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.839-47 (April 1983).
A space-charge model for electrolyte transport in charged capillary pores was examined experimentally with aqueous solutions of alkali chlorides and $MgCl_2$ in track-etched mica membranes. The model combines the Gouy-Chapman view of the double layer with the Nernst-Planck and Navier-Stokes transport equations. The pores of experimental membranes were uniform capillaries with a well-characterized cross section. The pore sizes ranged from an order of magnitude smaller to an order of magnitude larger than the Debye screening lengths of solutions. Three independent quantities were measured: streaming potential, for which an applied pressure across the membrane is the driving force for transport; pore conductivity, for which an applied electrical potential is the driving force; and concentration potential, for which an electrolyte concentration difference is the driving force. Data follow the trends of model predictions but indicate that chloride ions affect the pore wall charge. For monovalent cations, the pore wall charge deduced from pore conductivity measurements yielded theoretical predictions for the streaming potential and for the concentration potential that agree quite well with the data. Such agreement was not obtained with Mg^{2+}, probably because these divalent cations adsorbed onto the negative pore wall. In the absence of strong interaction between the charged pore wall and free ions in solution, the model is quantitatively accurate for pores larger than 30Å in radius and for aqueous electrolyte concentrations of 0.1M or lower. (19 refs.)

66.60 THERMAL CONDUCTION IN NONMETALLIC LIQUIDS

(for thermal conduction in liquid metals, see 72.15C)

72173 An equation for thermal conductivity of heavy water. J.Yata, T.Minamiyama (Kyoto Inst. of Technol., Kyoto, Japan).
Mem. Fac. Ind. Arts Kyoto Tech. Univ. Sci. & Technol. (Japan), vol.31, p.14-30 (Dec. 1982). [received: May 1983]
An equation for the thermal conductivity of heavy water (D_2O) is formulated in the temperature range up to 600°C and in the pressure range up to 3000 bar, based on the reliable experimental data available at present. Comparisons between the calculated values by the equation and the experimental data are given both in the liquid and vapor states. The degree of uncertainty of the equation is estimated to be 2~3% in the liquid state, 2~5% in the vapor state and of the order of 10% in the critical region, in the pressure range up to 1000 bar. In the pressure range from 1000 to 3000 bar, the degree of uncertainty is estimated to be 3~5% below the critical temperature and 5~10% above the critical temperature. The values of the thermal conductivity of heavy and ordinary water are compared by using the present equation for

heavy water and the previous one for ordinary water. The thermal conductivity of heavy water is shown to be smaller in the high density region and larger in the low density region than that of ordinary water. (18 refs.)

(for thermal conduction in solid metals, see 72.15C and 72.15E; for statistical mechanics of lattice vibrations, see 63.70)

72174 Low temperature heat transfer studies on exfoliated vermiculite. C.R.Maiti (Cryogenic Engng. Centre, IIT, Kharagpur, India).
Indian J. Cryog., vol.7, no.4, p.168-72 (1982).
A radial heat flow type cylindrical calorimeter guarded at both ends has been fabricated for measuring apparent mean thermal conductivity of powder insulation. Measurements have been made on a number of particle sizes of exfoliated vermiculite at different vacuum levels over the temperature range of 300 to 77K. The results indicate that exfoliated vermiculite may be profitably used in low cost cryogenic insulation system. (4 refs.)

72175 Lattice thermal conductivity of II-VI compounds. R.D.Bijalwan (Phys. Dept., Garhwal Univ. Campus, Tehri, India), P.N.Ram, M.D.Tiwari.
J. Phys. C (GB), vol.16, no.13, p.2537-45 (10 May 1983).
The lattice thermal conductivity of four II-VI compounds, ZnS, ZnSe, ZnTe and CdTe, has been analysed on the basis of the Callaway formalism in the temperature range 2-300K taking separate contributions of longitudinal and transverse phonons. In the analysis the phonon scattering from boundary, point defects, and three-phonon processes has been considered. In the three-phonon processes the relaxation times having different temperature dependence in different temperature ranges have been used in the calculation. It is observed that the contribution of transverse phonons to the thermal conductivity is more than that of longitudinal phonons at all temperatures. Good agreement with the experimental results has been obtained. (19 refs.)

72176 Thermal conductivity of HgSe. S.M.Wasim, B.Fernandez, R.Aldana (Dept. de Fisica, Univ. de Los Andes, Merida, Venezuela).
Phys. Status Solidi a (Germany), vol.76, no.2, p.743-6 (16 April 1983).
The thermal conductivity of HgSe is measured at low temperatures. The pronounced depression in the magnitude of the thermal conductivity above 4K and other anomalous behaviour observed by other workers at higher temperatures are explained by taking into account the additional scattering of phonons by extended defects or clusters in Callaway's formalism. (12 refs.)

72177 Thermal conductivity of corundum, high-alumina, magnesia, zirconium, and chromate refractories in the 400-1800°C range. 67.50 FERMI FLUIDS; LIQUID HELIUM-3

72178 Resonant pulse propagation of sound in superfluid ^{3}He-*B*. O.Avenel (Service de Phys. du Solide et de Resonance Magnetique, CENS, Gif-sur-Yvette, France), M.Rouff, E.Varoquaux, G.A.Williams.
Phys. Rev. Lett. (USA), vol.50, no.20, p.1591-4 (16 May 1983).
Superfluid ^{3}He-*B* offers a unique example of level crossing, that of the zero-sound mode and the internal 'real squashing' mode of the gap parameter. A full treatment of this classic problem is given which compares well with observations at 1.2 bars and 45 MHz. The characteristic beat pattern seen on-resonance is identified as a '0π-area' pulse, first discussed by Crisp (1970). The present findings for the signal velocity agree with Brillouin's well-known predictions. (13 refs.)

67.80 SOLID HELIUM AND RELATED QUANTUM CRYSTALS

72179 Wetting of FCC ^{4}He grain boundaries by fluid ^{4}He. J.P.Franck, K.E.Kornelsen, J.R.Manuel (Dept. of Phys., Univ. of Alberta, Edmonton, Alberta, Canada).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1463-5 (9 May 1983).
The observation of polygonated thin films of FCC ^{4}He in contact with the fluid is described. Partial melting of the polygonated structure allows the observation of the dihedral angle of fluid helium at a grain boundary. The fluid is shown to wet the grain boundaries almost completely. 67.90 OTHER TOPICS IN QUANTUM FLUIDS AND SOLIDS (E.G. NEUTRON-STAR MATTER)

72180 On the possibility of attaining the Bose-condensation region in spin-polarized atomic hydrogen at ultra-low temperatures. Yu.Kagan, G.V.Shlyapnikov (Kurchatov Inst. of Atomic Energy, Moscow, USSR).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.309-12 (9 May 1983).
It is shown that the adsorption of atomic hydrogen on the He^4 surface is predominantly accompanied by excitation of the surface wave. At ultra-low temperatures a strong decrease in the adsorption rate with temperature is found to result in a surface density of adsorbed atoms essentially lower than its equilibrium value. Therefore the channels of recombination of atomic hydrogen on the surface prove to be suppressed and it becomes possible to make compatible the Bose-condensation and the long lifetime of the spin-polarized atomic hydrogen gas. (17 refs.)

68.10 FLUID SURFACES AND INTERFACES WITH FLUIDS

(inc. surface tension, capillarity, wetting and related phenomena)

72181 Systematics of metal-insulator interfacial energies: a new rule for wetting and strong catalyst-support interactions. A.M.Stoneham (Theoretical Phys. Div., AERE, Harwell, England).
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.249-59 (March 1983).
This work concerns three questions: How can one decide whether a particular liquid metal will wet a given oxide substrate? What does analysis of experimental data tell one about the nature of the metal-substrate interactions? Is there correlation with strong metal-support interactions in catalysis? Comparison of the trends predicted by the continuum results of Barrera and Duke (1976) with those observed shows that the dispersion contribution to metal-oxide interfacial energies cannot be the only important term. From the observed trends for non-reactive metal-oxide systems one deduces: (i) Wetting should be favoured by a low metal plasma frequency (i.e. low electron density). (ii) Wetting should be favoured by a small insulator bandgap. (iii) The insulator refractive index is especially useful as a classifier. It appears to be a rule that only for substrates with $n^2 \gtrsim 4.5$-5 does one find wetting by most non-reactive metals. The same rule is found for strong metal-support interaction, which should therefore correlate with wetting. (iv) Trace impurity effects are very pronounced whenever the impurity effects have potential consequences in many applied problems, including substrate effects in support catalysts, liquid phase sintering and liquid metal embrittlement. (21 refs.)

72182 On the calculation of solid-liquid interfacial tension in metallic systems from contact angle data. N.Eustathopoulos (Lab. de Thermodynamique et Phys.-Chimie Metall., ENSEEG, Saint Martin d'Heres, France), A.Passerone.
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.107-200 (May 1983).
Two main techniques are usually employed to determine solid-liquid interfacial tensions, σ_{SL}, in multicomponent metallic systems: it is calculated from contact angle measurements and from dihedral angle determinations. The first technique is faster and easier to use, but usually yields results which do not agree with those derived from the latter. This problem is discussed by a critical analysis of two sets of data referring to the same systems, namely solid zinc in contact with bismuth, indium, lead and tin melts. (19 refs.)

72183 The pressure tensor at the planar surface of a liquid. J.P.R.B.Walton, D.J.Tildesley, J.S.Rowlinson, J.R.Henderson (Phys. Chem. Lab., Univ. of Oxford, Oxford, England).
Mol. Phys. (GB), vol.48, no.6, p.1357-68 (20 April 1983).
The planar surface of a liquid of molecules with truncated Lennard-Jones potentials has been simulated at two temperatures. The normal component of the pressure tensor, $p_N(z)$, is shown to be a constant, independent of the height z. There are many possible definitions of the transverse component, $p_T(z)$; two of these are computed and are shown to differ by small but significant amounts. All definitions of $p_T(z)$ give the same value of the surface tension, but they lead to different values for the apparent height of the surface of tension, that is the height at which the tension is supposed to act. The difference is about 0.3-0.5 d, where d is the molecular collision diameter, for the two choices of $p_T(z)$ considered here. (18 refs.)

72184 Critical wetting in three dimensions. E.Brezin, B.I.Halperin (Phys. Dept., Harvard Univ., Cambridge, MA, USA), S.Leibler.
Phys. Rev. Lett. (USA), vol.50, no.18, p.1387-90 (2 May 1983).
A critical wetting (or interface delocalization) transition occurs when the interface between two fluid phases becomes infinitesimally bound to an attracting wall. It is shown that the critical exponents at this transition depend continuously on the parameter $\omega \equiv k_B T_w / (4\pi \xi_b^2 \sigma)$, where σ is the surface tension of the free interface, ξ_b is the bulk correlation length in the attracted fluid phase, and T_w is the transition temperature. (12 refs.)

72185 How corundum refractories are wetted by molten steel. A.E.Zhukovskaya, A.A.Kortel', E.A.Sherman, E.A.Prokof'eva, T.P.Korableva (All-Union Inst. of Refractories, USSR).
Refractories (USA), vol.23, no.9-10, p.504-7 (Sept.-Oct. 1982). Translation of: *Ogneupory (USSR)*, vol.23, no.9, p.50-3 (Sept. 1982). [received: May 1983]
Corundum refractories, modified with additions of Mg, Cr, and Zr oxides and silicon-containing substances designed for making the tiles of gate valves, were studied for the wettability by steel 45 at 1550°C. It was established that the incorporation of oxides of Zr, Cr; mixtures of Cr, Mg and Zr oxides; and also silicon-containing additives, increases the wetting angle of corundum refractories. The low wettability of these refractories by steel determines to a signif-

icant degree the high metal resistance in service of the gate-valve tiles. (8 refs.)

72186 Fluid droplet movement on a solid surface in a temperature gradient field. A.S.Dzyuba.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.549-53 (April 1983). In Russian.
The behaviour of fluid droplets on a solid surface is analyzed in temperature gradient. It is found that the droplets move on the surface in the direction of low temperature. A linear relationship is obtained for the droplet velocity vs. size. Coalescence in an ensemble of moving droplets of different sizes is observed under collision conditions. The coalescence is governed by the droplet velocity-size dependence. Size and temperature gradient limitations are found for the movement of droplets. (13 refs.)

68.15 LIQUID THIN FILMS

72187 Measurement of liquid film profiles by moire topography. H.S.Kheshgi, L.E.Scriven (Dept. of Chem. Engng. & Materials Sci., Univ. of Minnesota, Minneapolis, MN, USA).
Chem. Eng. Sci. (GB), vol.38, no.4, p.525-34 (1983).
Area-wide surface topography is continuously monitored with the moire technique, i.e. measurement of patterns formed by superposition of the warped image of a line grating on a similar reference grating. A simple method for reconstructing liquid film profiles from moire fringe patterns is developed. The method is tested with a known specimen, a convex lens. Leveling of an uneven liquid film by gravity and capillary force is followed and film profiles are measured at intervals of time. Waves flowing down an inclined plate and disturbances in a liquid curtain are viewed, as are small disturbances caused by the impingement of tiny surface-active particles. Possible application to control of coating operations is pointed out. (21 refs.)

72188 Laser-induced thermohydrodynamic effects in thin liquid membranes. G.Da Costa, F.Bentolila, E.Ruiz (Dept. de Fisica, Univ. Simon Bolivar, Caracas, Venezuela).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.313-15 (9 May 1983).
Thermocapillary effects are produced in liquid membranes suspended from rigid contours by heating with a 1 mW, focused laser beam. This induces pits with diameter 0.1 mm and lifetime 1 h after termination of heating. Self-modulation of the reflected and transmitted laser beams is reported. (9 refs.)

68.20 SOLID SURFACE STRUCTURE

72189 The effect of ion beams on the composition of $Cu_2O(111)$ surfaces. J.Herion, G.Scharl, M.Tapiero (Inst. fur Grenzflachenforschung und Vakumphys., KFA, Julich, Germany).
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.233-48 (March 1983).
$Cu_2O(111)$ surfaces were studied under conditions typically used in Auger depth profiling, i.e., under electron and ion bombardment. Compositional changes were measured with AES as a function of energy and mass of the ions. By increasing the ion energy from 0.5 to 4 keV and the atomic weight of the bombarding gas from 20 to 131, an increase of the oxygen-to-copper ratio by about 1% and 2.5%, respectively, was obtained. The Auger line shapes were not markedly influenced by a change of the ion energy. The oxygen-to-copper ratio increased by several percent during ion bombardment of a sample which was prepared by cleaving in situ. Heating to at least 150°C leads to a decrease of the oxygen enrichment as well as of the concentration of implanted Ar. No electron beam effects could be detected in these experiments. (24 refs.)

72190 The mechanism of the surface stabilization of CrO_2 magnetic powders. F.Garbassi, E.M.Ceresa (Novara Res. Center, Istituto Guido Donegani Spa, Novara, Italy), G.Basile, G.C.Boero.
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.330-50 (March 1983).
Previously (see Meter. Res. Bull, vol.17, p.1197, 1982). A new process for the stabilization of CrO_2 powders against degradation of magnetic properties has been proposed, based on a thermal treatment in the temperature range of 573-663K in an inert gas atmosphere. In this work, the authors have studied the modifications induced by the stabilization process on the CrO_2 acicular particles in order to clarify the mechanism by which the stabilization takes place. It was found that the bulk properties of CrO_2 are not noticeably affected, suggesting that only some surface layers are involved, and that the formation of massive reduced phases does not take place. Thermal analysis and XPS data showed how the surface is modified and which transformations are responsible for the stabilization. These transformations are related to and affect the different species of chromium and oxygen ions. The main reactions involved are the dehydration of β-CrOOH, the disproportionation of Cr^{4+} surface ions and the decrease of the surface concentration of the reactive OH^- groups. On the basis of this study, the authors suggest that modifications of the ion population of the superficial layers are sufficient for obtaining a good stability of the CrO_2 particles. (33 refs.)

72191 Surface compositions of copper-silicon alloys. T.C.Frank, J.L.Falconer (Dept. of Chem. Engng., Univ. of Colorado, Boulder, CO, USA).
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.359-74 (March 1983).
Auger spectroscopy of copper-silicon alloys showed that silicon is enriched at the surface of both an ordered compound, Cu_3Si, and a solid-solution alloy (5 at.% Si). The surface compositions are estimated using elemental standards. Silicon segregation is predicted by thermodynamic theories based on surface tensions of pure components and by the empirical Burton and Machlin rule. The Si(92 eV) Auger peak splits into two peaks upon alloying, making identification of alloyed silicon possible. Surface silicon is in an alloyed form for both Cu_3Si and $Cu_{0.95}Si_{0.05}$. Above 670K, additional silicon segregates to the surface of Cu_3Si and both alloyed and elemental silicon are present. Alloying copper with silicon results is weakened silicon bonds and clean Cu_3Si oxidizes much more rapidly in air than does elemental silicon. This weakened bonding may be one reason that copper catalyzes the reaction between methyl chloride and silicon to form methylchlorosilanes. (41 refs.)

72192 Study of thermal equilibrium in the neighbourhood of an imperfect contact surface between two solid bodies. H.Lanchon, B.Makaya, J.Saint Jean Paulin (Lab. d'Energetique et de Mecanique Theorique et Appliquee, CNRS, Nancy, France).
C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.8, p.597-600 (28 Feb. 1983). In French.
Using homogenization techniques, the authors study the influence of the roughness distribution at the interface between two solid media, on the thermal (or electrical) transfer between these two bodies. They obtain in particular the thermal contact resistance. (2 refs.)

72193 Oxygen and sulphur influence upon segregation at a nickel-chromium alloy surface. P.Humbert, A.Mosser (Lab. de Cristallographie, ERA, Strasbourg, France).
C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.8, p.601-4 (28 Feb. 1983). In French.
Segregation phenomena induced by oxygen on a (111) face of a nickel-chromium alloy (30% Cr) during oxidation and following vacuum annealing have been studied by Auger Spectroscopy. Both with a clean and a sulphur-covered surface, the results show a chromium enrichment provided the temperature allows sufficient mobility of surface atoms. Sulphur enhances this segregation. (7 refs.)

72194 Thermal rearrangement of surface of spherical nickel single crystal. N.A.Gorbatyi, S.Pulatova (Lenin Tashkent State Univ., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.74-7 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1295-9 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The equilibrium form of a crystal surface is taken to be the form of the crystal that is in thermodynamic equilibrium with its own vapor; in this case the free surface energy (FSE) is minimal for the given crystal volume. The surface configuration that satisfies the condition of minimum FSE is a Wulff polyhedron, that reflects the anisotropy of the specific surface energy (SSE). The authors examine rearrangement of the surface of spherical nickel single crystal in the process of high-temperature heating in an atmosphere consisting of the crystal's own vapor. (10 refs.)

72195 Microgeometry of contact surfaces through anisotropy assessment. N.Idrus (Royal Melbourne Inst. of Technol., Melbourne, Victoria, Australia).
IEEE Trans. Components, Hybrids & Manuf. Technol. (USA), vol.CHMT-6, no.1, p.60-5 (March 1983). (28th Annual Holm Conference on Electrical Contacts, Chicago, IL, USA, 13-15 Sept. 1982).
In order to predict accurately the electrical and thermal characteristics of contacting surfaces, a surface and thus three-dimensional (rather than a profile-based) specificiation of the contacting microgeometries is required. A method is described by which a three-dimensional assessment of the surface microgeometry is made using a minimum number of radial traverses of the surface. Hitherto, many parallel traverses had to be recorded for the same purpose. A computer simulation shows that the proposed method is highly promising. (9 refs.)

72196 Mean inner potentials of aluminium and copper. M.A.Ochando, A.Sanchez, C.R.Serna (Dept. de Fisica del Estado Solido, Univ. Complutense, Madrid, Spain).
J. Phys. C (GB), vol.16, no.13, p.L401-3 (10 May 1983).
Reflection high-energy electron diffraction patterns were taken from electropolished (100), (110) and (111) surfaces of aluminium and copper. From the displacements of the spots compared with the Bragg position the mean inner potentials were obtained, being 13.2 V for aluminium and 19.1 V for copper. (20 refs.)

72197 Scanning tunneling microscopy. G.Binnig, H.Rohrer (IBM Zurich Res. Lab., Ruschlikon, Switzerland).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.236-44 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Scanning tunneling microscopy, a novel technique based on vacuum tunneling, yields surface topographies in real space and work function profiles on an atomic sale. Surfaces are shown for Au(110), Si(111) and GaAs(111). (9 refs.)

72198 Multilayer relaxation in metallic surfaces as demonstrated by LEED analysis. H.L.Davis, J.R.Noonan (Solid State Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.245-52 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Theoretical motivations are reviewed for investigation of multilayer relaxation in relatively simple metallic surfaces. Results from LEED analysis are presented which serve to demonstrate that multilayer relaxation measurably exists in Cu(100) and Cu(110) surfaces. The results from two independent LEED analyses for Cu(110) are shown to be in much better agreement with each other than the LEED results are with multilayer relaxation results obtained by high energy ion scattering. Multilayer relaxation results for other metallic surfaces also are reviewed briefly, and all available results are discussed in relationship to those obtained by a theoretical, model-type, inquiry of Landman et el. (1980). (15 refs.)

72199 He diffraction studies of Pt(110) (1×2). A.M.Lahee, W.Allison, R.F.Willis (Dept. of Phys., Univ. of Cambridge, Cambridge, England), K.H.Rieder.
Surf. Sci. (Netherlands), vol.126, no.1-3, p.654-60 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Results are presented on the diffraction of ^{4}He atoms from the 1×2 reconstructed surface of Pt(110). The diffraction pattern observed indicates that the surface can be considered to have a one-dimensional corrugation. From the position of the rainbow maximum the corrugation amplitude is estimated to be $\sim$1.5 Å. Structural models for the surface are used to derive corrugation functions from the superposition of atomic charge densities. The results of hard wall scattering calculations from these large corrugations are compared with the experimental data. The results confirm that the large corrugation amplitude could arise from a displaced or missing row model. However, limitations in the present analytical theory prevent any definite distinction to be made concerning the detailed nature of the atomic displacements. These limitations are discussed in the light of the present results and previously published data. (11 refs.)

72200 Study of the Ag(110) surface by He diffraction. A.Luntz, L.Mattera, M.Rocca, S.Terreni, F.Trommasini, U.Valbusa (Istituto di Sci. Fisiche, Univ. di Genova, Genova, Italy).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.695-701 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The scattering of He beams from the Ag(110) surface has been studied for two beam energies and several angles of incidence. The analysis of the experimental data shows that the softness of the interaction potential must be carefully considered. A soft corrugated wall potential model which allows fast and accurate calculations is presented. The force parameter and the surface corrugation, strongly dependent on the incident energy, are derived as best fit parameters and do favourably compare with the values obtained by close-coupling calculations. The peak-to-peak corrugation is found to be significantly larger than for Ni(110) and Cu(110) surfaces. (11 refs.)

72201 Surface segregation in Pt-Cu alloys. A.D.van Langeveld, V.Ponec (Gorleans Lab., Rijksuniv. Leiden, Leiden, Netherlands).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.702-7 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Platinum-copper alloys, prepared by standard metallurgical techniques, cleaned and annealed in ultra high vacuum, were analyzed by Auger electron spectroscopy. The surface segregation of Cu was found to be only moderate. In the calculations of the surface composition from the Auger spectra Gallon's (1969) model was used, whereby corrections were made for differences in the backscattering coefficients and the different matrix densities of both metals. (17 refs.)

72202 Study of organic surfaces with UPS and metastable deexcitation spectroscopy. C.Reynaud, C.Juret, C.Boizau (Service de Phys. des Atomes et des Surfaces, CENS, Gif-sur-Yvette, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.733-8 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Studies a thin polyacrylonitrile film by metastable deexcitation spectroscopy, associated to UPS. Since it is purely superficial and a non-desctructive spectroscopy, MDS appears to be very well suited to the study of organic surfaces. The PAN sample is grafted on an Fe support by electropolymerization, a process which guarantees well-characterized and reproducible samples. The PAN reticulation produced by heat-treatment at $T=200°C$ appears clearly on the MDS spectra. The layer conductivity is better after the reticulation. The acrylonitrile molecular orbital energies seem to be weakly modified by the polymerization. (12 refs.)

72203 The atomic geometry of GaAs(110) revisited. C.B.Duke, S.L.Richardson, A.Paton (Xerox Webster Res. Center, Webster, NY, USA), A.Kahn.
Surf. Sci. (Netherlands), vol.127, no.2, p.L135-43 (April 1983).
Improvements in surface structure determination methodologies based on the analysis of experimental low-energy electron diffraction intensities are utilized to perform an R-factor structure determination for GaAs(110). In addition to the commonly-accepted structure (a top-layer bond-length-conserving rotation of the As outward and the Ga inward characterized by $\omega_1=27°$, relaxation of the top layer toward the bulk by 0.05 Å, and a relaxation of the second-layer Ga outward and As inward by 0.06 Å), a new structure is found which consists of a top-layer bond-length-conserving rotation of $\omega_1=7°$, relaxation of the top layer away from the bulk by 0.05 Å, and a converse second-layer relaxation of the Ga and As by 0.03 Å. This new structure may be distinguished from the accepted one and refinements thereof by examining the integrated intensities of the diffracted beams. When these are considered, a refinement of the accepted structure still provides the best description of measured low-energy electron diffraction intensity data, and is manifestly compatible with other recent analyses of photoemission and isochromat data. (15 refs.)

72204 A helium diffraction study of the reconstructed Au(100) surface. K.H.Rieder, T.Engel, R.H.Swendsen (IBM Zurich Res. Lab., Ruschlikon, Switzerland), M.Manninen.
Surf. Sci. (Netherlands), vol.127, no.2, p.223-42 (April 1983).
The reconstructed Au(100) surface has been investigated using He-diffraction techniques. The topmost layer is found to have a dominant (1×5) periodicity, whereby the corrugation appears one-dimensional in the direction of the longer unit cell. The complex LEED patterns observed for this surface must be due to secondary structural features such as minor atomic displacements in the topmost or lower layers. Several reconstruction models were considered and surface electron density calculations were performed to enable a comparison with the corrugation functions deduced from the He-diffraction data. (39 refs.)

72205 LEED intensity analysis of the (1×5) reconstruction of Ir(100). E.Lang, K.Muller, K.Heinz (Inst. fur Angewandte Phys., Lehrstuhl fur Festkorperphys., Univ. Erlangen, Erlangen, Germany), M.A.Van Hove, R.J.Koestner, G.A.Somorjai.
Surf. Sci. (Netherlands), vol.127, no.2, p.347-65 (April 1983).
A new LEED structural analysis is carried out for the (1×5) reconstruction of Ir(100). It is based on a recent set of experimental I-V curves obtained with a computer-controlled video camera. Special attention is paid to reproducibility and reliability, and an R-factor analysis is now included. The previously preferred structure (a buckled top layer that is quasi-hexagonally closed-packed and involves bridge sites) is confirmed with minor positional adjustments comparable to the uncertainty of the method. The other structural models that have been examined can clearly be rejected. (23 refs.)

68.25 MECHANICAL AND ACOUSTICAL PROPERTIES OF SOLID SURFACES AND INTERFACES

(for tribology, see 62.20P and 81.40P)

72206 Propagation of transversal surface acoustic waves (SAW) under heavy periodic electrodes in Y-cut quartz. E.Danicki.
Pr. Inst. Tele- & Radiotech. (Poland), no.92, p.5-19 (1983). In Polish.
Presents a propagation theory of transversal surface acoustic waves in piezoelectric substrate with deposited heavy metal electrodes on its surface. It was assumed that the mechanical properties of the electrodes should not be neglected. The analysis of the dispersion interrelations for waves near the synchronism with the electrodes has shown considerable effect of the electrodes mass on the shape and the mutual position of the stop bands for electrodes electrically closed and electrically short circuited. These considerations are based on the approximated effective surface impedance connecting the amplitudes of harmonic waves of electric fields and mechanical fields observed on the surface of piezoelectric substrate. Parameters of this approximation for Y-cut quartz substrate are given. The presented considerations are directly applicable to the theory of skimming acoustic wave devices. (21 refs.)

68.30 DYNAMICS OF SOLID SURFACES AND INTERFACE VIBRATIONS

72207 Multiphonon surface processes. Sun Hur-bin, Tsai Chien-hua (Inst. of Solid State Phys., Nanjing Univ., Nanjing, China).
Commun. Theor. Phys. (China), vol.1, no.1, p.19-25 (1982).
In catalysis and other surface phenomena, besides affording static influences, such as modifications in energy spectra and wave functions of atoms and molecules in chemisorbed states in contrast with those in free states, the substrate may also show its existence by participating in the dynamics. The present article intends to call attention to a class of multiphonon processes. The mechanism is explained through the discussion of a few examples. (3 refs.)

72208 Vibrations in superlattices; application to GaAs-AlAs systems. J.Sapriel (CNET, Bagneux, France), B.Djafari-Rouhani, L.Dobrzynski.
Surf. Sci. (Netherlands), vol.126, no.1-3, p.197-201 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Bulk and surface vibrations in GaAs-AlAs superlattices are studied. The dispersion curves of propagating waves along the direction perpendicular to the layers are investigated for several values of the ratio of the layers thicknesses and comparisons are made between the results of the elasticity theory and those of a microscopic model of two alternating diatomic sublattices of GaAs and AlAs. For a number of monolayers larger than 5 and for the first branches of the dispersion curves, the two models give the same results. The conditions of existence of acoustic shear waves localized at the free surface of the superlattice are investigated theoretically and numerically with the help of the elastic model. (5 refs.)

72209 The spectroscopy of surface vibrations in ionic crystals by inelastic scattering of atoms. G.Benedek (Istituto di Fisica, Univ. di Milano, Milano, Italy).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.624-40 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The recent progress in the production of highly monochromatic atomic beams is paving the way for a full determination of the surface vibrational structure. Account is given of the recent determination of Rayleigh wave dispersion curves from angular distributions exploiting the kinematical focusing effect. A short review is then presented on the direct measurement of surface phonon dispersion curves. A comparison is made with the existing theories of surface phonons in ionic crystals. The one photon energy loss spectra of He scattering from LiF(001) calculated for a hard corrugated surface model are found to be in general good agreement with the experimental TOF spectra. Evidernce is obtained that: (i) one-phonon processes are predominant, and (ii) in addition to Rayleigh waves important contributions to the inelastic scattering come from the surface projected density of bulk phonons. Important effects due to inelastic resonances with surface bound states are put in evidence and explained by simple kinematical arguments. The possible observation of surface optical modes in NaF(001) is discussed. (51 refs.)

68.40 SURFACE ENERGY OF SOLIDS; THERMODYNAMIC PROPERTIES

72210 Surface free enthalpy in multilayer surface descriptions. L.Z.Mezey, J.Giber (Inst. of Phys., Budapest Tech. Univ., Budapest, Hungary).
Surf. Sci. (Netherlands), vol.127, no.1, p.L98-101 (April 1983).
The surface free enthalpy is shown to have layer contributions on the basis of the additivity of the free enthalpy function. The contribution of the topmost layer is shown to be the largest by theoretical considerations. Numerical calculations on real binary alloys show that only about 0.01-0.10% is associated with the layers under the topmost one. (6 refs.)

68.45 SOLID-FLUID INTERFACE PROCESSES

(see also 82.65 Sorption and accommodation coefficients)

72211 Thermally induced negative ion ESD. J.H.Craig,Jr. (Dept. of Phys., Univ. of Nebraska, Omaha, NE, USA).
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.382-6 (March 1983).
Electron stimulated desorption of O^- has been observed from oxygen on platinum. Negative ion ESD is not observed during oxygen uptake at 300K. However, O^- emission occurs during heating after oxygen exposure. Comparison is made with previously measured O^+ ESD from this system. The negative ion results are discussed in terms of electron attachment and polar dissociation mechanisms. An ion energy distribution for O^- is also presented which exhibits a peak considerably broader than the previously measured O^+ IED. (11 refs.)

72212 Molecular dynamics study of the interlayer water in phyllosilicates. P.Demontis, E.S.Fois, A.Gamba, B.Manunza, G.B.Suffritti (Inst. of Phys. Chem., Univ. of Sassari, Sassari, Italy).
THEOCHEM (Netherlands), vol.10, p.245-54 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).
A preliminary molecular dynamics study of the interlayer water in montmorillonite was performed by using a central force interaction model. The structural properties of the system, deduced from distribution functions, and the IR spectrum of water, calculated by Fourier transform of dipole moment autocorrelation function, are presented and compared with experimental data. (25 refs.)

72213 Anomalous sorption kinetics curves and Fick diffusion. M.A.Mirkin (Leningrad Gov. Univ., Leningrad, USSR).
Vysokomol. Soedin. Ser. B (USSR), vol.25, no.3, p.197-200 (1983). In Russian.
The absorption of liquids by polymers in a state of strain is governed by a diffusion coefficient which is time dependent, and determined by relaxation processes of relatively long duration. A modified form of Fick's diffusion law is proposed to account for this phenomenon, which predicts absorption curves with points of inflexion. The modified equation is used to model water absorption by isotactic polypropylene at 6×10^4 kPa pressure and 293K. It is shown that the model can be fitted closely to experimental data. These data cannot be fitted by the classic Fick's law equation. (1 ref.) *C.J.S.*

72214 Adsorption of oxygen and cesium by lanthanum hexaboride. D.A.Gorodetskii, V.K.Tskhakaya, Yu.G.Shchudlo, V.I.Yarygin, A.A.Yask'ko.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.6-10 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1224-9 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Slow electron diffraction and Auger electron spectroscopy are employed to investigate adsorption of oxygen on the surface of LaB_6(100). Oxygen forms a c (2×2) structure in the process of adsorption at room temperature. (7 refs.)

72215 Use of SED method to investigate phenomena on ordered and defect parts of single-crystal surfaces. D.S.Rumi, S.Zh.Nimatov (Arifov Inst. of Electronics, Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.15-19 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1235-9 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Slow electron diffraction (SED), electron-stimulated desorption (ESD), and mass spectrometry in an ultrahigh vacuum are used to investigate the phases of oxygen adsorption on a real (111) surface of Si single crystal. (9 refs.)

72216 Adsorption and electron state of CO, NO, and O_2 on Pt and Ir: Investigation by photoelectron spectroscopy and thermodesorption. A.I.Boronin, P.A.Zhdan (Inst. of Catalysis, Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.27-31 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1247-51 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors have employed electron spectroscopy and thermodesorption to investigate the electron state of CO, NO and O_2 adsorbed on the surface of recrystallized Pt and Ir foils. Comparison of the data obtained by these methods made possible a detailed characterization of the state of the adsorbates, and also an examination of the processes that take place on Pt and Ir surfaces in the temperature range 300-800K. (16 refs.)

72217 Adsorption and electroadsorption of oxygen on {111} and {113} faces of monocrystalline germanium. T.P.Smirnova, V.G.Ivanov.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.32-5 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1252-5 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Field-emission microscope studies of adsorption of oxygen on germanium have revealed a substantial increase in the adsorption rate when a strong electric field of autoionic sign is present. It has been shown that, under these conditions, there is a marked change in the form of the field-emission (FE) image of a germanium surface that has been cleansed by desorption by an electric field, and also that has been heated at the temperature of final rearrangement. In the neighborhood of the {100}, {111} and {113} faces weakly emitting areas appear, the integral current decreases substantially, and the increase in the work function amounts to 1.8 eV. These changes have been accounted for in terms of changes in the nature of filling of the germanium surface in a strong electric field and formation of a dense adsorption covering as a result of the fact that strong electron fields deform and disrupt the bonds on the surface and in the surface region of semiconductors, and increase the number of adsorption centers. (5 refs.)

72218 Adsorption of lithium on the surface of germanium single crystal. G.I.Bigun, I.D.Nabitovich, Yu.S.Sikhorskii (Lvov Polytech. Inst., Lvov, Ukrainian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.36-9 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1256-9 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The field-emission method is used to investigate adsorption of lithium on the surface of the (100) and (111) faces of germanium single crystal. The concentration dependences of the work function and the binding energy for 'zero' covering are obtained. (15 refs.)

72219 Adsorption of barium on the (110) and (111) faces of molybdenum. U.V.Azizov, S.T.Sabirov, S.T.Dzhalilov (Lenin Tashkent State Univ., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.40-4 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1260-4 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors investigate adsorption of barium on the (110) and (111) faces of molybdenum by the methods of thermoelectronic emission and surface ionization of cesium. It is established that adsorption of barium for constant concentration on the (110) and (111) faces of Mo is of a reconstruction nature with increasing substrate temperature. (11 refs.)

72220 Some features of thermodesorption of oxygen from molybdenum. U.V.Azizov, V.S.Gutov, Ya.R.Sagatov.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.45-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1265-8 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Thermodesorption and electron-stimulated desorption employing a time-of-flight mass spectrometer as a partial pressure detection are used to investigate the kinetics of oxygen adsorption on molybdenum. (7 refs.)

72221 Adsorption of aluminum on low-resistance gallium arsenide. E.I.Blazhnova, N.V.Mileshkina, G.B.Nazarov (Leningrad State Univ., Leningrad, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.194-6 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1420-2 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Adsorption of aluminum was investigated using low-resistance crystals of n-type gallium arsenide with a resistivity $\rho\sim10^{-3}$ ohm.cm, $n=8.6\times10^{17}$ cm^{-3}, and tin doping. The surface of single crystals, cut in the ⟨111⟩ direction, was purified by desorption using a strong electric field in a hydrogen atmosphere. GaAs field-emission cathodes manufactured in this fashion were characterized by stable emission and reproducible volt-ampere characteristics (VAC) of the field-emission current. When aluminum was deposited on the reference tungsten tip, the field-emission current increased in accordance with the decrease in the work function of the surface, while the volt-ampere characteristics shifted into the region of lower anode voltages. (7 refs.)

72222 An examination of adsorbed oxygen molecules on Ag(110) by UPS. M.A.Barteau, R.J.Madix (Dept. of Chem. Engng., Stanford Univ., Stanford, CA, USA).
Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.85-8 (6 May 1983).
The nature of the chemisorbed state of molecular oxygen on Ag(110) was studied by ultraviolet photoemission. The results show that the molecular orbital structure of O_2(gas) is strongly altered in contrast to O_2 adsorbed on aluminum. These results are consistent with previous studies utilizing vibrational spectroscopy. (20 refs.)

72223 An extended Huckel study of hydrogen and oxygen chemisorption on Ru(001) surface. B.C.Khanra, S.K.Saha (Solid State & Molecular Phys. Div., Saha Inst. of Nuclear Phys., Calcutta, India).
Chem. Phys. (Netherlands), vol.76, no.2, p.255-8 (15 April 1983).
Extended Huckel MO theory has been applied to treat the chemisorption of hydrogen and oxygen atoms on Ru (001) surfaces. The site of chemisorption, surface-adatom distance, chemisorption energy and the vibrational frequency of the adatom on the surface have been calculated. For different sites, the chemisorption energy (E_c) results are as follows: For hydrogen, $|E_c|$(centre)$>|E_c|$(top)$>|E_c|$(bridge); while for oxygen, $|E_c|$(bridge)$>|E_c|$(top)$>|E_c|$(centre). These results are critically discussed in the light of recent results obtained from electron energy-loss spectroscopy (EELS) experiments. (25 refs.)

72224 Rotationally mediated selective adsorption as a probe of isotropic and anisotropic molecule-surface interaction potentials: HD(*J*)/Ag(111). Chien-fan Yu, C.S.Hogg, J.P.Cowin, K.B.Whaley, J.C.Light, S.J.Sibener (Dept. of Chem., Univ. of Chicago, Chicago, IL, USA).
Isr. J. Chem. (Israel), vol.22, no.4, p.305-14 (1982).
Rotationally mediated selective adsorption scattering resonances are used to make an experimental and theoretical study of the laterally averaged interaction potential between HD and a weakly corrugated system, Ag(111). The experimentally observed resonances determine the vibrational levels of the HD/Ag(111) physisorption potential as a function of bound rotational state. These vibrational levels show J-dependent shifts due to the orientational anisotropy of the potential. Exact quantum scattering calculations using a full laterally averaged potential of the form $V_0(z,\theta)=\nu_0(z)[1+\beta P_2(\cos\theta)]$ have been carried out to obtain rotationally inelastic transition probabilities. Experimental and theoretical resonance energies are compared for two forms of $\nu_0(z)$, a Morse and a variable exponent potential, as a function of β, and are found to be very close to the first-order perturbed energies of a free rotor in bound states of $\nu_0(z)$. Both potential forms give equally good fits to the data, yielding an optimum value of the asymmetry parameter, $\beta\approx-0.05$. The determination of β is relatively insensitive to small changes in the $\nu_0(z)$ well depth. (38 refs.)

72225 NonMarkoffian theory of activated rate processes. II. Thermal desorption. A.Nitzan, B.Carmeli (Dept. of Chem., Tel Aviv Univ., Tel Aviv, Israel).
Isr. J. Chem. (Israel), vol.22, no.4, p.360-4 (1982).
For pt.I see Phys. Rev. Lett., vol.49, no.7, p.423 (1982). A model for thermal desorption, described by a one dimensional classical generalized Langevin equation (GLE) for the motion of an adatom, is solved by reducing the GLE to a Fokker-Planck equation in action space. The escape rate is obtained as the inverse mean first passage time for the particle to achieve a threshold energy (or action). A calculation using parameters corresponding to the desorption of Ar from W is compared with quantum mechanical results for the same model. (12 refs.)

72226 Interaction of NO_2 with a Pt(111) surface. J.Segner, W.Vielhaber, G.Ertl (Inst. fur Phys. Chem., Univ. Munchen, Munchen, Germany).
Isr. J. Chem. (Israel), vol.22, no.4, p.375-9 (1982).
The interaction of NO_2 with a Pt(111) surface was studied by molecular beam and thermal desorption techniques. At 300K NO_2 adsorbs dissociatively

into $NO_{ad}+O_{ad}$ with an initial sticking coefficient $s_0=0.97$. s_0 decreases slightly with increasing surface temperature; the variation of the sticking coefficient with coverage exhibits a marked 'precursor' state behavior. The rate of formation of gaseous NO is limited by desorption of this molecule, i.e. there is no evidence for a direct process $NO_2 \rightarrow NO_g+O_{ad}$. At ≈400K NO desorption is complete and only O_{ad} is building up on the surface. The maximum coverage $\theta_{0,max} \approx 0.77$ is much higher than that so far reported for exposure to O_2 (0.25), which is ascribed to kinetic effects, i.e. a much higher sticking coefficient in the case of NO_2. Two additional states with desorption energies of about 32 and 38 kcal/mol characterize the high oxygen coverage situation. Desorption of O_2 starts above 450K. (27 refs.)

72227 Dynamics of surface atoms and molecules under irradiation. Y.Shapira (School of Engng., Tel Aviv Univ., Ramat Aviv, Israel).
Isr. J. Chem. (Israel), vol.22, no.4, p.386-94 (1982).
Various classes of interactions between surface species and irradiation are discussed. Electron induced decomposition of halides, photon-and electron-stimulated desorption and photodesorption are emphasized. Experimental work, involving a wide range of techniques, has been carried out on different materials whose surfaces can be subject to those interactions, enhancing our insight into the corresponding processes. The data are described in terms of existing and new mechanisms, while the similarities and differences between the various interactions are pointed out. (58 refs.)

72228 Strong adsorption in critical binary mixtures. L.Peliti, S.Leibler (Istituto di Fisica 'G. Marconi', Univ. di Roma, Roma, Italy).
J. Phys. C (GB), vol.16, no.13, p.2635-40 (10 May 1983).
Field theoretical calculations of the order parameter profile in the critical adsorption problem in binary fluids are discussed. The irrelevance of van der Waals interactions with the wall and the validity of the strong adsorption limit are established. Results are compared with those of other existing approaches. (11 refs.)

72229 Transient diffusion kinetics in media exhibiting axial variation of diffusion properties. I. Sorption kinetics. Z.J.Grzywna, J.H.Petropoulos (Phys. Chem. Lab., Democritos Nuclear Res. Centre, Athens, Greece).
J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.4, p.571-84 (April 1983).
Transient unidimensional sorption of a penetrant in a medium exhibiting a gradation in diffusion properties along the diffusion axis is considered. The effect of the mode and extent of the variation in diffusion properties on the kinetics of both 'symmetrical' and 'unsymmetrical' sorption processes is investigated systematically by numerical solution of a number of carefully chosen representative cases. A previous asymptotic analytical treatment is reconsidered, corrected where necessary, and further developed. Its practical usefulness is then assessed by comparison with the corresponding numerical results. The insight thus gained should permit a much more systematic and informative analysis of the transient sorption kinetic behaviour of experimental nonhomogeneous solid-penetrant systems. (13 refs.)

72230 Transient diffusion kinetics in media exhibiting axial variation of diffusion properties. II. Permeation kinetics. Z.J.Grzywna, J.H.Petropoulos (Phys. Chem. Lab., Democritos Nuclear Res. Centre, Athens, Greece).
J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.4, p.585-97 (April 1983).
For pt.I see ibid., vol.79, no.4, p.571 (1983). Transient-state permeation of a penetrant across a slab or membrane exhibiting a gradation in diffusion properties along the diffusion axis is investigated by the methods used in the preceding analogous study of sorption kinetics. Early- and late-time transient permeation kinetics at both upstream and downstream surfaces of the membrane have been examined, in turn, in a systematic manner. Proper analysis of data of this kind (hitherto largely unexploited in experimental practice) is potentially capable of furnishing important information about the mode and extent of the spatial variation of diffusion properties, which partly parallels and partly augments the information deducible from sorption kinetics or permeation time lags. The results of this and the preceding paper provide much of the theoretical background necessary for the practical use of transient-state analysis in a manner analogous to the method of time-lag analysis previously developed. (13 refs.)

72231 Partially dissociative adsorption of water vapor on the Si(111)(7×7) surface. H.Kobayashi, T.Kubota, M.Onchi, M.Nishijima (Dept. of Chem., Kyoto Univ., Kyoto, Japan).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.345-6 (9 May 1983).
High-resolution vibrational electron energy-loss spectra have been measured of the Si(111)(7×7) surface exposed to water vapor at 300K. Direct experimental evidence is given that water adsorption on the Si(111)(7×7) surface is partially dissociative. (8 refs.)

72232 Evidence for pseudo bridge bonding of $c(2\times2)$-O on Ni(100). J.E.Demuth, N.J.DiNardo, G.S.Cargill,III (IBM Res. Center, Yorktown Heights, NY, USA).
Phys. Rev. Lett. (USA), vol.50, no.18, p.1373-6 (2 May 1983).
New low-energy electron-diffraction intensity measurements and dynamical calculations indicate that oxygen in a $c(2\times2)$ overlayer resides 0.80 ± 0.025 Å above the top layer of Ni atoms and is displaced 0.30 ± 0.1 Å from the fourfold hollow position along a $\langle110\rangle$ direction. This produces a structure having C_{2V} symmetry with two inequivalent nearest-neighbor Ni-O bond distances of 1.75 ± 0.05 and 2.14 ± 0.08 Å. (21 refs.)

72233 Adsorption of carbon monoxide on osmium (0001): development of a nonhexagonal structure model. N.Vennemann, E.W.Schwarz, M.Neumann (Fachbereich Phys., Univ. Osnabruck, Osnabruck, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.273-8 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The chemisorption of CO on osmium (0001) at 200K has been investigated by means of low-energy electron diffraction (LEED) and temperature programmed desorption (TPD). The CO is adsorbed rapidly forming a well-ordered $(\sqrt{3}\times\sqrt{3})$ R30° pattern after an exposure of 2.3×10^{-4} Pa s, corresponding to a coverage of $\theta=1/3$. After an exposure of 2.8×10^{-4} Pa s, an 'intermediate' pattern, corresponding to $1/3<\theta<5/12$, is observed. For larger exposures the overlayer compresses continuously until saturation coverage at $\theta=0.63$ is reached. Due to a combined LEED/TPD investigation, relative coverages could be determined, leading to the suggestion of a nonhexagonal structure model for CO adsorption on Os(0001) in the compression range. A hexagonal structure model could clearly be ruled out. (16 refs.)

72234 Orientation of water adsorbed on Cu(110). C.Mariani, K.Horn (Fritz-Haber-Inst., Max-Planck-Gesellschaft, Berlin, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.279-85 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The method of determining the orientation of an adsorbed molecule by angle-resolved photoemission with polarised light has been applied to the case of water adsorbed on clean copper (110). By using dipole selection rules and symmetry arguments, it is found that in the full monolayer as well as at submonolayer coverages, the water molecules are adsorbed in a tilted geometry. Only small shifts in the valence photoemission peak relative to the gas phase spectrum are found, indicative of a weak chemisorption bond. These results are explained, by recourse to LEED observations, in terms of recent models of water layers on metal surfaces. (15 refs.)

72235 On the interaction of oxygen with Pt single crystals: LEED study of step coalescence. G.Lindauer, P.Legare, G.Maire (Lab. the Catalyse et Chimie-des-Surfaces, Univ. Louis Pasteur, Strasbourg, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.301-6 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Several single crystal faces of platinum, after decontamination, are exposed to oxygen pressures from 10^{-9} to 10^{-6} Torr in a range of temperatures between 25 to 800°C. The adsorption is studied by LEED and Auger spectroscopy. Oxygen is adsorbed on all platinum surfaces. The existence of defects like steps, terraces or ledges strongly facilitates the dissociation and the adsorption of oxygen. On Pt(111) stepped surfaces, two types of (2×2) structures are obtained: one at room temperature, very sensitive to the electron beam, disappears on heating at 100°C in UHV. A more stable (2×2) is observed at 400°C. Under these experimental conditions, a step coalescence and a terrace broadening is induced by oxygen depending on the terrace orientation. For example, the terrace width and the step height are doubled on the Pt[6(111)×(100)]. (11 refs.)

72236 Adsorbate interactions in energetics, structure, dynamics, and kinetics of adlayers: CO and N_2 on Ru(001). D.Menzel, H.Pfnur, P.Feulner (Phys. Dept., Tech. Univ. Munchen, Garching, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.374-81 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
In order to show the influence of lateral as well as 'vertical' interactions on adsorbate properties, coverage dependent data for energies and entropies of adsorption, order-disorder transitions, vibrational and electronic coupling, and kinetics of adsorption and desorption are correlated for CO and (partly) for N_2 on Ru(001). These two systems appear to be quite similar in many respects, like TPD spectra, coverage dependence of thermodynamic data, and formation of $\sqrt{3}$ structure, which are all caused by the existence of strong nearest-neighbour (NN) repulsion and weak next-nearest-neighbour (NNN) attraction in both systems. However, completely opposite behaviour is observed for the sticking coefficients, s, as function of coverage. While for CO, s drops sharply between $0.2<\theta<0.33$ at most temperatures, N_2 shows a sudden jump of s to about twice the initial value in the same coverage range. Closer examination shows that the contrary behaviour is connected to the different evolution of the layers in addition to the $\sqrt{3}$ (NNN) coverage. While for CO, compression of the chemisorbed layer sets in after complete filling of the $\sqrt{3}$ structure, resulting in a layer with roughly identical molecules at each coverage, for N_2 a very different binding state close to physisorption is formed even before the $\sqrt{3}$ structure is fully developed. In both cases influences of the properties of the chemisorbed layer (in particular its statistical distribution, as determined by phase transitions) on those of transient precursors or physisorbed species become important. (24 refs.)

72237 Interaction of hydrogen with a palladium (110) surface. M.G.Cattania, V.Penka, R.J.Behm, K.Christmann, G.Ertl (Inst. fur Phys. Chem., Univ. Munchen, Munchen, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.382-91 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The adsorption of hydrogen on a Pd(110) surface was investigated using Video-LEED, work function ($\Delta\phi$) and thermal desorption mass spectroscopy (TDS) techniques. At 120K, dissociative adsorption occurs readily with a sticking probability near unity. The formation of a 'true' ordered (2×1) hydrogen phase corresponding to $\theta_H=1.0$ is followed by a (1×2) phase with intense LEED spots indicating a H-induced surface reconstruction. The work function of the clean surface increases continuously with H exposure, up to a saturation value of 325 mV. TDS reveals a total of four hydrogen binding states. Two high-temperature states β_1 and β_2 are produced by chemisorbed H, whereas the low-temperature states α_1 and α_2 only occur on the reconstructed surface and are tentatively attributed to H atoms that have moved to subsurface sites located below the topmost Pd atom layer. The energy splitting of the α states possibly indicates two different kinds of subsurface sites or two different desorption mechanisms; the α_1 site is progressively populated as the surface reconstruction proceeds. (14 refs.)

72238 Temperature programmed field desorption of protonated hydrogen from rhodium and tungsten. N.Ernst, J.H.Block (Fritz-Haber-Inst. der Max-Planck-Gesellschaft, Berlin, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.397-404 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The reaction of hydrogen, induced by an electric field of about 20 V/nm, on rhodium and tungsten field emitter surfaces is investigated by means of mass and appearance spectroscopy equipped with a new scanning technique. Generation of H_3^- on protruding single atoms is studied by comparing surface temperature dependences for H_3^+ and D_3^+ formation rates. Field-adsorbed hydrogen species display different surface-temperature behaviour on W and Rh. This is ascribed to the population of field-induced molecular binding sites which differs for the two metals. The formation of H_3^+ is discussed within the frame of a surface reaction model involving field-adsorbed H_2(f-ad) and chemisorbed H(ad): $H_2(\text{f-ad})+H(\text{ad}) \rightarrow H_3^+(g)+e^-(\text{Me})$. (23 refs.)

72239 Desorption of F and Cl from A (110)Mo surface: binding energies and pre-exponential factors. G.Bolbach, J.C.Blais (Inst. Curie, Section de Phys. et Chimie, Paris, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.405-9 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
A systematic study of the binding energy of halogens on the (110), (100) and (111) Nb, Mo, Ta and W surfaces has been undertaken in order to predict the nature of the chemisorption bonding of such adatoms on transition metal surfaces. The results concerning F and Cl on (110) Mo are presented. Under low coverage conditions ($\theta<10^{-2}$ of a monolayer), first order desorption kinetics have been observed and the mean adsorption lifetime τ has been determined. Since the general expression $\tau=\tau_0 \exp(E/kT)$ is verified in a large temperature range (1700-2300K), the binding energy E and the pre-exponential factor can be deduced: $E(F)=4.6\pm0.1$ eV, $\tau_0(F)=8\times10^{-14}$ s; $E(Cl)=4.1\pm0.1$ eV, $\tau_0(Cl)\simeq5\times10^{-14}$ s. These values are similar to those previously reported on (100) and (111) Mo surfaces; thus for the system studied, the binding energy of a given halogen does not depend on the surface orientation. (13 refs.)

72240 The interaction of CO with Al(111) at room temperature. K.Khonde, J.Darville, J.M.Gilles (Dept. de Phys., Facultes Univ. Notre-Dame de la Paix, Namur, Belgium).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.414-21 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
AES, LEED, low resolution ELS and work function measurements were conducted at room temperature on the interaction of CO with Al(111). Three main stages in the adsorption process were observed. Dissociative adsorption led to the incorporation of oxygen and carbon with the formation of amorphous oxidized and carburized aluminium. The initial state of the sample surface strongly determines the adsorption kinetics. In this framework the authors discuss the effect of structural defects and chemical impurities. (5 refs.)

72241 Kinetics of carbon monoxide adsorption on Re(0001) between 100 and 300K. S.Tatarenko, R.Ducros, M.Alnot (LARIGS, Lab. Maurice Letort, CNRS, l'Univ. de Nancy I, Villers-les-Nancy, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.422-8 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Carbon monoxide adsorption has been studied by Thermal Programmed Desorption, Auger Electron Spectroscopy and Low Energy Electron Diffraction on Re(0001) between 100 and 300K. Three α states and one β state with first order kinetics are observed. The α species correspond to CO molecularly adsorbed and the β species to molecules partially dissociated. Annealing of the adsorbed layers at several temperatures has shown that the β species is formed during heating process. Coadsorption with O_2 has shown that the CO layer is only adsorbed on some parts of the surface. At saturation the adsorbed layer is compact and adsorption takes place through a mobile precursor weakly bound to the surface. (27 refs.)

72242 Coadsorption of water and ions on Cu(110): models for the double layer. K.Bange, D.Grider, J.K.Sass (Fritz-Haber-Inst. der Max-Planck-Gesellschaft, Berlin, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.437-43 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The coadsorption of oxygen, bromine and sodium with water on Cu(110) has been studied using ultraviolet spectroscopy, thermal desorption spectroscopy, measurements of work function changes and low energy electron diffraction. Compared to the clean surface, these ionic coadsorbates give rise to striking modifications of the adsorption behaviour of water, with a pronounced dependence on submonolayer coadsorbate coverage. Possible electrochemical implications of these results, in particular with regards to the electric double layer formed at the metal-electrolyte interface are briefly discussed. (16 refs.)

72243 Desorption of negative ions on metallic samples by very low energy electrons. M.Bernheim, M.Chaintreau, R.Dennebouy, G.Slodzian (Lab. de Phys. des Solides, Univ. Paris-Sud, Orsay, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.610-17 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Electro-stimulated experiments were performed in a classical microscope for secondary ion emission; the immersion collection lens is providing a very good collection of the ions emitted with low initial energies. The electron beam decelerated just as the sample neighbourhood is bombarding the target with a low and easily adjustable energy and with a high density nearly independent of the electron energy. The variations of desorption yields with electron energy and energy distributions of the desorbed ions could be recorded directly. Among the preliminary results one should emphasize: (i) The desorbed H^- yields exhibit a sharp peak at low energies depending on the metal of the sample. (ii) The O^- desorption yield is modified by the electron energy during the adsorption process; the desorption curves show distinct changes in their slopes. (iii) H^- and O^- ions are emitted with very low initial energies; their spread in energy remains nearly independent of the incident electron energy. (7 refs.)

72244 Adsorption of H_2O on Al(111). F.P.Netzer, T.E.Madey (Surface Sci. Div., NBS, Washington, DC, USA).
Surf. Sci. (Netherlands), vol.127, no.1, p.L102-9 (April 1983).
The adsorption of H_2O on Al(111) has been studied by ESDIAD (electron stimulated desorption ion angular distributions), LEED, AES and thermal desorption in the temperature range 80-700K. At 80K, H_2O is adsorbed predominantly in molecular form, and the ESDIAD patterns indicate that bonding occurs through the O atom, with the molecular axis tilted away from the surface normal. Some of the H_2O adsorbed at 80K on clean Al(111) can be desorbed in molecular form, but a considerable fraction dissociates upon heating into OH_{ads} and hydrogen, which leaves the surface as H_2. Following adsorption of H_2O onto oxygen-precovered Al(111), additional OH_{ads} is formed upon heating, and H_2 desorbs at temperatures considerably higher than that seen for H_2O on clean Al(111). The general behavior of H_2O adsorption on clean and oxygen-precovered Al(111) ($\theta_O \lesssim$monolayer) is rather similar at low temperature, but much higher reactivity for dissociative adsorption of H_2O to form OH_{ads} is noted on the oxygen-dosed surface around room temperature. (16 refs.)

72245 Comparison of H^+ and H^- ESD from hydrogen on platinum. J.H.Craig,Jr. (Dept. of Phys., Univ. of Nebraska, Omaha, NE, USA).
Surf. Sci. (Netherlands), vol.127, no.1, p.175-81 (April 1983).
Electron desorption of H^- from H_2 adsorbed on platinum is observed and compared with the corresponding H^+ emission. The H^- signal is observed to track closely with the thermal desorption signal indicating a possible correlation between production of molecular hydrogen prior to desorption and formation of H^- from polar dissociation. The energy distribution and thresholds for H^+ and H^- are observed to be significantly different. The H^- threshold is shown to be 7-8 eV higher than for H^+. (15 refs.)

72246 Small absorbate dipole moments need not imply small charge transfers. N.D.Lang (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
Surf. Sci. (Netherlands), vol.127, no.2, p.L118-22 (April 1983).
It is pointed out that small, electronegative adatoms like H and O are able to exhibit very small dipole moments even though they may show appreciable charge transfer. This is true because the spatial separations of charge involved can be far less than 1 Å. (9 refs.)

72247 Nickel carbonyl adsorption on the Ni(111) surface. J.L.Gland, R.W.McCabe, G.E.Mitchell (Phys. Chem. Dept., General Motors Res. Labs., Warren, MI, USA).
Surf. Sci. (Netherlands), vol.127, no.2, p.L123-8 (April 1983).
Overlayers formed by the adsorption of $Ni(CO)_4$ in CO on the Ni(111) surface at 100K were characterized using high resolution electron energy loss spectroscopy and thermal desorption spectroscopy. At temperatures below 135K, molecular nickel carbonyl adsorbs on the CO saturated Ni(111) surface as suggested by several observations. Vibrational transitions characteristic of molecular $Ni(CO)_4$ are dominant. The energy dependence of both the elastic and inelastic electron scattering cross sections are dramatically altered by $Ni(CO)_4$ adsorption. All of the mass spectrometer ionization fragments typical of molecular $Ni(CO)_4$ are observed in the narrow thermal desorption peak at 150K. The inelastic scattering cross sections for both adsorbed nickel carbonyl and adsorbed CO on the Ni(111) surface suggest that a nonresonant dipole scattering mechanism is dominant. (15 refs.)

72248 Interaction of O_2 with low index faces of α-CuZn. S.Maroie, P.A.Thiry, R.Caudano, J.J.Verbist (Lab. de Spectroscopie Electronique, Facultes Univ. Notre-Dame de la Paix, Namur, Belgium).
Surf. Sci. (Netherlands), vol.127, no.2, p.200-22 (April 1983).
The adsorption of O_2 and initial step of oxidation have been investigated, mainly at room temperature, for three different α-CuZn (75%Cu/25%Zn) surfaces (110), (100) and (111) by XPS, XAES, LEED, CPD and HREELS. No superstructures were detected on the LEED patterns during O_2 admission for the three faces, and from the beginning of adsorption Zn segregated to the surface. For (110), the interaction of oxygen follows the sequence: (1) dissociative chemisorption (up to ~20 L), accompanied by an increase of the work function and a single site occupancy as revealed by HREELS; (2) nucleation of ZnO only, indicated by a decrease of the work function, a shift of the Zn $L_3M_{45}M_{45}$ Auger transition and an emergence of a vibration at 550 cm^{-1}, corresponding to the surface phonon of ZnO. The (111) face follows the same scheme, except that the sticking coefficient for oxygen is very low. For (100), it is clear that two states of oxygen exist simultaneously, even at the beginning, as revealed by HREELS and CPD measurements. No copper oxides are ever detected, even after heat treatment. In addition, different bonding properties of OH groups on the three surfaces are reported. (43 refs.)

72249 On the adsorption of oxygen on the Mo{110} surface and its vicinals. E.Bauer, H.Poppa (Stanford/NASA Joint Inst. for Surface & Microstructure Res., NASA Ames Res. Center, Moffett Field, CA, USA).
Surf. Sci. (Netherlands), vol.127, no.2, p.243-54 (April 1983).
The adsorption of oxygen on a Mo{110} surface and four vicinal planes with steps parallel to ⟨100⟩, ⟨110⟩ and ⟨111⟩ directions is studied by Auger electron spectroscopy (AES) and low energy electron diffraction (LEED). The work has the goal to elucidate whether O adsorption on Mo{110} is really as different from O adsorption on W{110} as reported, and what is the cause of the apparent discrepancies between the various reported sticking coefficients on stepped surfaces. (18 refs.)

72250 Conditions for stabilization of carbon monoxide near the surface of KCl and KBr crystals. B.M.Trakhbrot (Inst. of Phys., Acad. of Sci., Tbilisi, Georgian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1785-6 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3149-51 (Oct. 1982). [received: April 1983]
During the thermal bleaching of additively colored KCl and KBr crystals various kinds of interactions occur between the electron color centers, molecules adsorbed from the gas phase and impurities in the lattice. This article presents results of optical studies of the conditions for the formation and stabilization of carbon monoxide in KCl and KBr crystals in consequence of the adsorption of CO_2 molecules. (7 refs.)

72251 Desorption of excited atoms and molecules stimulated by synchrotron UV photons. N.Tolk, M.Traum (Bell Labs., Murray Hill, NJ, USA), N.Stoffel, G.Margaritondo.
Fifteenth Annual Synchrotron Radiation Users Group Conference (papers in summary form only received), Stoughton, WI, USA, 18-19 Oct. 1982 (Stoughton, WI, USA: Synchrotron Radiat. Center 1982), p.52
Recent observations of atomic and molecular optic radiation due to UV photon stimulated desorption of excited neutrals is discussed. Synchrotron radiation incident on surfaces is found to result in a surprisingly high yield of desorbed excited atoms (H*, Na* and Li*), more than 3 orders of magnitude larger than the yield of desorbed ions. (no refs.)

72252 Multilayer adsorption: a unified picture. M.Wortis, R.Pandit (Dept. of Phys., Univ. of Illinois, Urbana, IL, USA), M.Schick.
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.13-27
Reviews the theory of multilayer adsorption on attractive substrates. Emphasis is on understanding the systematics of behavior for a fixed adatom species over a range of adatom-substrate potential strengths. This point of view encompasses both thin and thick films, including coexistence phenomena such as wetting and roughening. Strong substrates exhibit layering and are always completely wet at coexistence. Intermediate substrates are incompletely wet at coexistence at low temperatures but become completely wet above a wetting temperature T_W. Weak substrates have finite gas-phase adsorption for all $T<T_c$. (31 refs.)

68.48 SOLID-SOLID INTERFACES

(inc. bicrystals; for grain boundaries, see 61.70N)

72253 XPS study of annealed SiO_2/GaAs interfaces. U.Konig, E.Sasse (AEG-Telefunken Forschungsinst. Ulm, Ulm, Germany).
J. Electrochem. Soc. (USA), vol.130, no.4, p.950-2 (April 1983).
SiO_2 has been deposited pyrolytically on GaAs of different orientations. The effects of annealing on these samples has been investigated with XPS. Between SiO_2 and GaAs, additional layers of Ga_2O_3 and As have been formed. Ga diffusion into SiO_2 is found. Orientation effects are discovered: the Ga amount in SiO_2 rises in the sequence from (111)B over (111)A to (100) and the As accumulation at the interface is more pronounced for (100). A simple model for oxidation and diffusion is proposed. (20 refs.)

72254 Structural intergrowths in the calcium lanthanum ferrites: $Ca_xLa_{1-x}FeO_{3-y}$ $(2/3<x<1)$. J.M.Gonzalez-Calbet, M.Vallet-Regi, M.A.Alario-Franco (Dept. de Quimica Inorganica, Univ. Complutense, Madrid, Spain), J.C.Grenier.
Mater. Res. Bull. (USA), vol.18, no.3, p.285-92 (March 1983).
Electron microscopy and diffraction studies of annealed samples in the $Ca_xLa_{1-x}FeO_{3-y}$ system $(2/3<x<1)$ show the existence of disordered intergrowths between $Ca_2Fe_2O_5$ and $(Ca_{2/3}La_{1/3})FeO_{8/3}$. A previous model for the structure of $(Ca_{2/3}La_{1/3})FeO_{8/3}$ is confirmed by high resolution images. Two types of interface boundary between both structures have been found. (13 refs.)

68.55 THIN FILM GROWTH, STRUCTURE, AND EPITAXY

(for techniques of crystal growth and film deposition, see 81.10 and 81.15)

72255 An ESD and SIMS study of the composition of platinized, antimony-doped tin oxide films. I. G.B.Hoflund, D.F.Cox (Dept. of Chem. Engng., Univ. of Florida, Gainesville, FL, USA), F.Ohuchi, P.H.Holloway, H.A.Laitinen.
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.281-96 (March 1983).
Secondary-ion mass spectrometry (SIMS) and electron-stimulated desorption (ESD) have been used to characterize the composition of antimony-doped tin oxide films before and after a caustic treatment and before and after deposition of platinum. The impurities were identified qualitatively using dynamic SIMS and found to be Li, C, N, Na, Mg, Al, Si, S, K, Ca, Cr, V, Fe, Mn, Ni, Ti and Zn. Both SIMS and ESD demonstrated that hydrogen is a major constituent of these films. Evidence is presented that the caustic treatment hydroxylates the surface and that Sb is segregated at the surface. It appears that platinum desorbs by electron stimulation probably in the form of an oxide species. This may prove useful in probing the composition of supported-metal crystallites. (61 refs.)

72256 Collision of a low-temperature laser plasma with a condensed medium. S.V.Gaponov (Inst. of Appl. Phys., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.139-44 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1170-6 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
Descriptions are given of the processes occurring in the plasma and solid that accompany the collision between a solid and products from laser erosion expanding under vacuum. The following may be decisive under particular interaction conditions: ionic sputtering, radiation-stimulated diffusion, production of amorphous surface layers on annealing in these, and oriented film growth. It is shown that these phenomena can be used in controlling the properties of surface layers ($\Delta L=10\text{-}10^4$ Å). (22 refs.)

72257 Structure of stabilised ZrO_2 vacuum condensates. G.I.Batalin, V.K.Kushkov, O.V.Kachur, M.I.Grechanyuk.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.3, p.81-3 (1983). In Ukrainian.
Condensates of the ZrO_2-CaO system obtained by electron-beam evaporation and vacuum condensation onto molybdenum substrates were investigated by X-ray diffraction, electron microprobe analysis and scanning electron microscopy. The chemical composition of the vacuum condensates and dependence of the lattice constant of the ZrO_2-base cubic solid solution upon the substrate temperature are presented. (5 refs.)

72258 The effect of implantation of phosphorus into sputtered $MoSi_2$ thin films. T.P.Chow, C.S.Grant, W.Katz, G.Gildenblat, R.F.Reihl (General Electric Corporate Res. & Dev., Schenectady, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.933-8 (April 1983).
The effect of phosphorus implantation into DC magnetron sputtered $MoSi_2$ thin films is studied. The structural, compositional, and electrical properties are examined with X-ray diffraction, secondary ion mass spectrometry (SIMS), sheet resistance, and MOS measurements. A higher hexagonal to tetragonal $MoSi_2$ phase transition temperature is observed for implanted films than for unimplanted ones. At high fluence (5×10^{16} ions/cm^2), MoP is detected, with a significant increase in sheet resistance. Isothermal and isochronal annealing indicates a minimum temperature of 950°C, and a maximum fluence of 2×10^{16} ions/cm^2 can be used. Comparative *C-V* measurements show similar MOS characteristics between unimplanted and implanted films. (26 refs.)

72259 Properties of sputtered molybdenum silicide thin films. T.P.Chow, D.H.Bower, R.L.Van Art, W.Katz (General Electric Corporate Res. & Dev., Schenectady, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.952-6 (April 1983).
The structural, compositional, and electrical properties of molybdenum silicide (with an Si/Mo ratio between 2 and 2.3) thin films either sputtered from a hot-pressed, composite target or cosputtered from elemental targets are compared. Structural and compositional examination was performed with X-ray diffraction, Rutherford backscattering spectrometry (RBS), and secondary ion mass spectrometry (SIMS). X-ray diffraction revealed that the as-deposited silicide films were essentially amorphous but, after high temperature annealing, contained mostly tetragonal $MoSi_2$. SIMS depth profiling showed that the concentration of carbon and argon is lower in the cosputtered films but that of oxygen is higher than the alloy-sputtered films. This difference is attributed to the target purity and sputtering system configuration. Isothermal and isochronal annealing results in a minimum resistivity of ~100 $\mu\Omega$-cm in both cases. C-V measurements of silicide-gate capacitors with both types of films yielded similar values of work function and surface-state density. (19 refs.)

72260 Column structure of dielectric evaporated layers and some of their properties. T.Chudoba.
Jemna Mech. & Opt. (Czechoslovakia), vol.28, no.3, p.73-6 (March 1983). In Czech.
Problems encountered in applications of dielectric vacuum evaporated films in optics due to the specific structural properties of the deposited films are discussed. One of the main causes of instabilities of the optical parameters is the column structure of the evaporated films. The mechanism of the growth of the dielectric films and the influence of the deposition parameters on the structural and other properties of the films are discussed. These include refractive index, geometrical thickness of the film, transparency, dispersion, adhesion to the substrate, hardness and temperature and chemical stability. Amongst materials discussed are fluorides, sulphides and oxides. *E.D.*

72261 The effects of incorporating fluorine in amorphous germanium-silicon alloy films. R.Dutta, P.K.Banerjee, S.S.Mitra (Dept. of Electrical Engng., Univ. of Rhode Island, Kingston, RI, USA).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.149-57 (April 1983).
The structural, electrical and optical properties of RF sputtered fluorinated amorphous Ge-Si alloy films have been studied as a function of the amount of fluorine incorporated in the films. The results indicate an increased coordination in the binary semiconductor alloys with the increasing fluorine content. Fluorine attaches with extreme preference to silicon over germanium in the alloys. Due to this high preferential ratio, the increase in coordination on fluorination is much less than that observed in fluorinated amorphous silicon. The thermal stability of fluorinated alloys is found to be higher than similarly prepared hydrogenated samples. (8 refs.)

72262 Growth of a metal island film under conditions of non-steady-state reevaporation of metal adatoms. A.V.Rogachev, V.I.Lashkevich, V.V.Kharitonov (Belorussian Inst. of Railroad Engng., Gomel, Belorussian SSR).
J. Eng. Phys. (USA), vol.43, no.2, p.943-7 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.315-19 (Aug. 1982). [received: April 1983]
Taking into account the non-steady-state reevaporation of adatoms, the article solves the problem of diffusion growth of a system of uniformly distributed nuclei of the metallic phase. An expression describing the kinetics of change of the zone of nuclei capture is obtained. (9 refs.)

72263 Vapor phase epitaxial growth of ZnSe films. T.Muranoi, M.Furukoshi.
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.69-76 (1982). In Japanese.
Epitaxial layers of ZnSe have been grown on GaAs substrate using metallic Zn and metallic Se as the sources. The epitaxial growth was successful at temperatures T_{sub}:370 to 800°C. The thermal etching of the substrate in H_2 flow was necessary when the growth temperatures were in the range 370 to 450°C. When the substrate temperature and one of the source temperatures were fixed, the growth rate increased with the other source temperature and then saturated. Below the saturation point, the growth rate is proportional to the flow rate of each source material. Low resistivity films (of the order of 1 Ω.cm) were obtained at temperatures above 450°C. An electron probe microanalyser was used to determine the impurity profiles on the cleaved surfaces. Gallium and arsenic atoms were distributed exponentially throughout the films grown at 650 to 800°C with the concentration of 10^{20} cm^{-3}. The

gallium concentration was higher than the arsenic concentration. The resistivity of ZnSe on GaAs grown at temperatures 650 to 800°C became low because of Ga autodoping. (11 refs.)

72264 The effect of a continuous etch on the growth rate and morphology of InP prepared by the vapour phase epitaxial-hydride method. T.E.Erstfeld, K.P.Quinlan (Rome Air Dev. Center, RADC/ESM, Hanscom AFB, MA, USA).
J. Electron. Mater. (USA), vol.11, no.4, p.647-62 (July 1982). [received: Nov. 1982]
A study of the effect of a continuous in situ etch of HCl on growth rate and the properties of epitaxial InP layers prepared by the vapour phase epitaxial-hydride technique is reported. Growth rates were determined as a function of the following variables: HCl flow rates in the mixing and source zones PH_3 flow rates, and mixing zone temperatures. Epitaxial InP structures with good morphology were obtained when the continuous HCl etch was varied between 0.8 and 1.5 cc/min. The average values (77K) of the carrier concentrations and mobilities were 1.3×10^{15} cm^{-3} and 23000 cm^2 V^{-1} sec^{-1}, respectively. The study indicates that the continuous in situ HCl etch improves the quality of epitaxial InP layers. (24 refs.)

72265 Growth and characterization of Si doped vapor phase epitaxial GaAs for MESFET. M.Feng, V.K.Eu, T.Zielinski (Torrance Res. Center, Hughes Aircraft Co., Torrance, CA, USA), J.M.Whelan.
J. Electron. Mater. (USA), vol.11, no.4, p.663-88 (July 1982). [received: Nov. 1982]
Describes the Si-doping of GaAs that was grown using the $AsCl_3$:H_2:GaAs, Ga chemical vapour deposition process. The doping sources were $AsCl_3$:$SiCl_4$ liquid solutions which proved to be highly reproducible for Si doping within the range, 1×10^{16} to 2×10^{19} cm^{-3}. Incorporation of Si into the GaAs apparently occurs under near equilibrium conditions. This point is considered in detail and the consequences experimentally utilized to grow n, n^+ bilayers using a single $AsCl_3$:$SiCl_4$ doping solution. Si impurity profiles based upon differential capacitance and SIMS data are presented. These can be very abrupt for n, n^+ structures with order of magnitude changes occurring within 500 Å. For the 1×10^{16} to 8×10^{18} cm^{-3} doped samples the mobilities at 78 and 298K are comparable with the higher values reported for GaAs thin films grown by CVD. Power FET devices made from this material have demonstrated an output density of 0.86 watts/mm at 10 GHz. (20 refs.)

72266 Surface reaction of GaAs vapour phase epitaxy. H.Watanabe, T.Mizutani (Fundamental Res. Labs., Nippon Electric Co. Ltd., Kawasaki, Japan).
Oyo Buturi (Japan), vol.51, no.11, p.1216-25 (Nov. 1982). In Japanese. [received: March 1983]
In a review of GaAs vapour phase epitaxy the adsorption and reaction process whereby the surface layer matches the underlying crystal is examined. Research on the vapour phase epitaxial growth reaction depends on the measurement of reaction speed on adsorption, adsorption estimating and modeling and surface cover ratio calculation. From the adsorbed molecule distribution the atomic molecule distribution can be seen. All the available models and their theoretical basis are reviewed and evaluated. (33 refs.) *M.O.*

72267 Characterisation of compound semiconductor epitaxial layers. T.Ikoma, M.Taniguchi (Inst. of Industrial Sci., Univ. of Tokyo, Tokyo, Japan).
Oyo Buturi (Japan), vol.51, no.11, p.1226-37 (Nov. 1982). In Japanese. [received: March 1983]
The degree of mobility, purity of doping and deep layer comparison and estimation from the surface of compound semiconductor (II-V group) epitaxial layers are reviewed. Data on epitaxial layers of GaAs, $Al_xGa_{1-x}As_yP_{1-y}$ prepared using the LPE, VPE, MOCVD and MBE methods are discussed. InP, $In_xGa_{1-x}As$, $In_xGa_{1-x}As_yP_{1-y}$ are similarly reviewed and compared. The epitaxial methods used are evaluated. (140 refs.) *M.O.*

72268 The future of molecular beam epitaxy. K.Takahashi (Dept. of Phys. Electronics, Tokyo Inst. of Technol., Tokyo, Japan).
Oyo Buturi (Japan), vol.51, no.11, p.1295-6 (Nov. 1982). In Japanese. [received: March 1983]
Molecular beam epitaxy has entered the application phase because of its controllability and accuracy. Analogies are drawn between molecular beam epitaxy and current genetic engineering research. Advances in HEMT, band engineering and MOCVD are briefly outlined. (no refs.) *M.O.*

72269 Surface defects of closed-system-grown $Cd_xHg_{1-x}Te$ epitaxial layers. V.I.Ivanov-Omskii, V.K.Ogorodnikov, V.D.Rozumnyi (A.F. Ioffe Phys.-Tech. Inst., Acad. of Sci., Leningrad, USSR).
Phys. Status Solidi a (Germany), vol.76, no.1, p.71-4 (16 March 1983).
The interaction of the surface of the $Cd_xHg_{1-x}Te$ epitaxial layers grown by liquid phase epitaxy in a closed system with the vapor phase is studied. Depending on the actual system cooling procedures after the decanting of the solution, defects are found which appear on the epilayer surface in the form of drops of solidified solution or pits. These defects originate from processes associated with the condensation of the solution vapour. Planar surface epilayers can be obtained by properly controlling these processes. (6 refs.)

72270 Formation process in MnBi thin films by Williams' method. Y.Iwama, Y.Takeno (Dept. of Crystalline Materials Sci., Nagoya Univ., Nagoya, Japan).
Phys. Status Solidi a (Germany), vol.76, no.1, p.75-83 (16 March 1983).
Williams has found that when Mn and Bi are successively evaporated on a glass substrate, followed by prolonged annealing around 300°C, a ferromagnetic MnBi thin film can be obtained with its *c*-axis perpendicular to the film plane. In order to elucidate the formation process of the film, Rutherford backscattering (RBS) experiment, X-ray diffractometry, electron microscope study, and magnetic measurement are carried out. It is found that at the first stage of annealing up to 250°C a non-magnetic transitional compound $Mn_{1.2}Bi$ is formed, and during the subsequent annealing at 250°C, the final MnBi crystals with the aligned *c*-axes nucleate, and grow at the expense of the transitional phase. It seems likely that the last stage of reaction, a few Bi crystals remaining in the transitional phase may serve as the nuclei. (5 refs.)

72271 The lattice-pulling effect induced by the film stresses. Conditions of existence and discovery. Yu.B.Bolkhovityanov (Inst. of Semiconductor Phys., Acad. of Sci., Novosibirsk, USSR).
Phys. Status Solidi a (Germany), vol.76, no.1, p.85-93 (16 March 1983).
The growth conditions at which the lattice-pulling effect may be observed are examined. It is shown that there are different reasons such as the initial supercooling, the great growth velocity, and the non-prognosticated introducing of the substrate constituents into the liquid which can change the solid composition of a film expected during its growth. (21 refs.)

72272 Epitaxial regrowth of Si implanted (100) and (211) GaAs. R.S.Bhattacharya (Univ. Energy Systems, Dayton, OH, USA), A.K.Rai, S.C.Ling, P.P.Pronko.
Phys. Status Solidi a (Germany), vol.76, no.1, p.131-6 (16 March 1983).
Rutherford backscattering-channeling and transmission electron microscopy are used to investigate the annealing behavior of Si implanted GaAs layers. Undoped GaAs wafers of (100) and (211) orientations are implanted with 60 keV Si^+ ions to a dose of 1×10^{15} cm^{-2}. Capless, proximity annealing is performed in the temperature range 200 to 550°C. Two distinct annealing stages are observed for (100); one at 250°C which is associated with the onset of solid phase epitaxial growth and the other at 450°C which can be related to the annealing of microtwins. For (211), although the epitaxial regrowth starts at 250°C, the damage recovery rate is much slower compared to that for (100). Microtwins are the main residual defects after low temperature annealing in both (100) and (211) crystals. However, the microtwins are found to be more stable in (211) as compared to that in (100). (10 refs.)

72273 Isothermal liquid phase epitaxy. V.N.Lozovskii, V.P.Popov, N.V.Vlasenko (Novocherkassk Polytech. Inst., Rostov Region, USSR).
Prog. Cryst. Growth & Charact. (GB), vol.6, no.1, p.47-57 (1983).
The epitaxial growth of semiconductor solid solutions from a liquid phase appears to be possible under stringent isothermal conditions. The driving force of such epitaxy can be liquid phase supersaturation caused by isothermal mixing of liquidus solutions or supersaturation in the solid phase resulting from thermodynamic nonequilibrium of the substrate and the solution. The feature of the method is that film growth requires no control temperature and time of crystallization, while the film properties are set by the initial process conditions. Isothermal liquid phase epitaxy (ILPE) makes it possible to form hyperfine films whose component distribution can be controlled. ILPE inevitably starts on the initial stage of a common liquid phase epitaxy, therefore this phenomenon must be taken into consideration. The above mentioned factors account for the practical importance of the ILPE technique for modern electronics. The present paper reviews the mechanism as well as the main regularities of ILPE for A^3B^5 ternary alloys. (31 refs.)

72274 High resolution transmission electron microscopy investigation of adsorption and growth of Au on ZnTe surfaces. M.Shiojiri, N.Nakamura, C.Kaito (Dept. of Phys., Kyoto Tech. Univ., Kyoto, Japan), T.Miyano.
Surf. Sci. (Netherlands), vol.126, no.1-3, p.719-26 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The monolayer adsorption and the epitaxial growth of Au on the surface of ZnTe crystals have been examined by means of a multibeam lattice imaging technique in a 200 kV electron microscope with a pole piece of $C_s=1.2$ mm and by simulation using the multislice method. Au was vacuum-deposited to an average thickness of 0.5 nm onto 10 nm thick ZnTe films. It has been found that Au atoms are adsorbed on the Zn atoms of the (001)ZnTe surface to build a 1×1 monolayer structure. From the lattice images of the Au island particles together with those of the ZnTe substrates, the epitaxial relations and more precisely the positions of the Au lattice with respect to the substrate ZnTe lattice have been established. (10 refs.)

72275 Mechanism of coalescence of metal particles on a substrate. A.N.Pilyankevich, V.A.Mel'nikova (Inst. of Materials Sci., Acad. of Sci., Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.741-6 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.68-74 (Sept. 1982). [received: March 1983]
Acids were chosen as activators of transformations, and the mechanism of the process was investigated in discontinuous films of precious metals—gold and silver—in which islet growth takes place practically uniformly on the whole surface of a substrate. Films were applied to amorphous carbon and glass plates and to cleaved surfaces of ionic Ca_2 and NaCl single crystals by thermal vacuum deposition at a residual pressure of 2×10^{-3} Pa. It is concluded that the most acceptable model of the mechanism of metal particle coalescence in electrolytes is that of bulk migration of particles over the substrate surface, followed by their coalescence of agglomeration during collisions. (15 refs.)

72276 Metastable BCC phase in sputtered Fe-Ni alloys. K.Sumiyama (Dept. of Metal Sci. & Technol., Kyoto Univ., Kyoto, Japan), M.Kadono, Y.Nakamura.
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.190-4 (April 1983).
$Fe_{1-x}Ni_x$ alloy films obtained by the RF sputtering technique have been investigated by X-ray diffraction, magnetization and Mossbauer effect measurements. The single BCC phase extends up to about $x=0.4$, a BCC-FCC mixed phase appears for $0.4<x<0.5$ and a single FCC phase predominates for $x>0.5$. The lattice constants of the BCC and FCC phases are slightly larger than those of the bulk specimens. As a result of the BCC phase extension, both the magnetic moment and the Mossbauer spectrum of the Fe-Ni sputtered alloys change smoothly even in the BCC-FCC phase boundary region, in contrast to the results for bulk Fe-Ni alloys. (16 refs.)

72277 The investigation of zinc oxide film photodestruction by means of surface polariton spectroscopy and X-ray diffraction analysis. G.I.Dovbeshko, S.V.Ogurtsov, G.A.Puchkovskaya, M.T.Shpak.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.591-5 (April 1983). In Russian.
Surface polariton spectroscopy and X-ray diffraction analysis were employed to study laser radiation ($\lambda=0.63$ μm) effect on the ZnO film structure. Strong mechanical stresses were found in the films after radiation, which is associated with oxygen vacancies. The changes occurring in the ZnO film structure after laser radiation may be decreased by thermal annealing in a oxygen atmosphere. A conclusion is made that the X-ray diffraction analysis and surface polariton spectroscopy are sensitive methods for investigation of structural changes in films and laser annealing may be used for creating films with prescribed properties. (5 refs.)

72278 Effects of co-depositing oxygen on the growth morphology of (111) and (100) Al single crystal faces in thin films. P.B.Barna, F.M.Reicha, G.Barcza, L.Gosztola, F.Koltai (Res. Inst. for Tech. Phys., Hungarian Acad. of Sci., Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.25-30 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Correlation between the growth surface structure and the oxygen-to-aluminium flux ratio was found in vapour deposited Al films. Studies of the effect of co-depositing oxygen species on the growth surface structure were carried out in the case of epitaxially grown Al films (on NaCl, mica and GaAs substrates) containing crystals of (111), (100) and (110) orientations. On (111) crystal faces bunches of growth steps decorated by pinning sites, dents, macro steps correlating to grain boundaries and hillocks were developed. However, on (100) and (110) crystal faces only dents have been found. These results help to explain the correlation between the crystal face anisotropy in the surface micro-chemistry and anisotropy in the participation of

oxygen species in the growth mechanism on the various crystal faces. Whiskers and mushroom whiskers' were detected in Al films deposited at high level of oxygen contamination on amorphous substrates at first. Their formation can be ascribed also to these phenomena. (18 refs.)

72279 Investigation of metal evaporation by mass spectrometry. P.Glaser, E.Szigeti (Industrial Res. Inst. for Electronics, Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.31-4 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Electrical and mechanical properties of thin films are determined in addition to their material composition by the evaporation conditions. One of these conditions is the interaction between vapours and components of the residual gas. The aim of the study is to obtain reproducible film structures. To do this it is necessary to follow and to influence the changes of gas composition during evaporation and to recognize the components of the residual gas which are built into the film. The residual gas composition was investigated with low-resolution mass spectroscopy. The characteristic residual gas composition of the oil diffusion pumped system was determined, and changes of gas composition and partial pressure of certain gases were followed. Structure and electrical properties of films resulting from the controlled evaporation parameters were investigated. (4 refs.)

72280 Structure and electrical properties of amorphous Ni-P thin films [thin film resistors]. E.Besenyei, B.Zsoldos (Industrial Res. Inst. for Electronics, Budapest, Hungary), O.Geszti.
Vacuum (GB), vol.33, no.1-2, p.35-41 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Amorphous Ni-P films were prepared by electroless deposition. Electrical properties (sheet resistivity and temperature coefficient) of the resistance layer deposited on ceramic and glass substrates under various conditions were determined. The structure and morphology of the films were investigated by transmission electron microscopy and electron diffraction. A relationship was found between the structure and the electrical properties. In addition the effect of annealing, carried out at different temperatures, on the electrical properties of the resistance layer was studied. (10 refs.)

72281 Segregation phenomena in thin NiCr layers [thin film resistors]. M.Koltai, I.Trifonov, M.Czermann (Industrial Res. Inst. for Electronics, Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.49-52 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
In the case of NiCr resistor layers sputtered or evaporated a certain change occurs in their structure in the course of heat treatment and reactive deposition. The degree of this change depends on the parameters of deposition and heat treatment and it has a great effect on the TCR of the resistor layers. The depth profiles and electron-optical studies show a segregation of alloy components. Comparing the results of AES and electron-optical examinations to electrical parameters the authors can explain the positive shift of the TCR values by the segregation of the poorly conducting phases from the inside of the layers. (4 refs.)

72282 Electron microscopic and AES studies on thin layers of NiCr [thin film resistors]. L.Toth, A.Barna, G.Safran, M.Menyhard, T.Koranyi (Res. Inst. for Tech. Phys., Hungarian Acad. of Sci., Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.111-15 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
In order to understand the parameters affecting the properties of NiCr resistors prepared by various methods, the annealing properties of NiCr thin films were studied. TEM and electron diffraction were used to determine the structure of the films deposited onto SiO_x coated microgrids, while electrical measurements and AES in-depth profiling were carried out on the samples deposited under identical conditions onto silica substrates. The effect of a SiO_x protective coating on the structural changes was investigated during high temperature annealing in vacuum. In the NiCr samples annealed without a protective layer the selective oxidation of chromium led to a rather metallic type of conduction, while in the protected samples the stabilization of the conduction was observed after the same annealing. By hindering oxidation and surface diffusion processes the protective layer resulted in the development of a more stable structure in the NiCr films. (11 refs.)

72283 Diataxy (graphoepitaxy) and other approaches to oriented crystallization on amorphous substrates. E.I.Givargizov, N.N.Sheftal, V.I.Klykov (Inst. of Crystallography, Acad. of Sci., Moscow, USSR).
In book: *Current topics in materials science. Vol.10*, E.Kaldis [Ed.], p.1-53. Amsterdam, Netherlands: North-Holland (1982), vi+515 pp. [0 444 86321 4]
This review has shown how numerous and diverse the approaches are to oriented crystallization on amorphous substrates. In this diversity, two factors involved stand out as decisive for the oriented crystallization: the close-packed crystallographic planes and the presence of a liquid phase (melt or solution). The role of the first factor is, in general, understood. As for the second factor, its mechanism is far from clear. Many authors refer to the mobility of the atoms and/or crystallites on liquid surfaces. However, a drastic reduction of the surface energy for crystalline faces contacting a liquid phase seems to be also a very important factor in the oriented crystallization: this reduction facilitates two-dimensional nucleation and, hence, favors the layer growth mechanism and the orientation of overgrowth. 68.60 PHYSICAL PROPERTIES OF THIN FILMS, NONELECTRONIC

72284 Calorimetric studies of molecular layers of yellow arsenic. A.N.Rodionov, R.I.Kalendarev.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.111-14 (1983). In Russian.
Differential thermal analysis has been employed for studying phase transitions in molecular layers of yellow arsenic deposited on a substrate at 203K. The enthalpy change in reversible endothermic transition $As^1(I) \rightleftarrows As^2(I)$ was found to be equal $\Delta H_1 = 0.49 \pm 0.06$ kJ/mole, that of entropy $\Delta S_1 = 2.2 \pm 0.3$ J/K.mole; the enthalpy change for irreversible exothermic phase transition $As^2(I) \rightarrow As(II)$ (amorphization of yellow arsenic) was found to be equal to $\Delta H_2 = -(7.1 \pm 0.5)$ kJ/mole. The activation energy of the process was determined from amorphization kinetics and found to be equal to $E_a = 0.48 \pm 0.07$ eV. It is suggested that the enthalpy of amorphization of yellow arsenic is basically due to deformation of the As_4 molecule. (9 refs.)

72285 Diffusion-controlled deposition on fibers and surfaces. P.Meakin (Central Res. & Dev. Dept., E.I. du Pont de Nemours & Co. Inc., Wilmington, DE, USA).
Phys. Rev. A (USA), vol.27, no.5, p.2616-23 (May 1983).
Monte Carlo simulations have been carried out to investigate the deposition of particles on surfaces and fibers under conditions where the deposition is diffusion controlled. Deposits prepared under diffusion-controlled conditions have a completely different morphology from deposits prepared under conditions where diffusion is not important. For the case of deposition on thin fibers the authors find that the radius of gyration of the deposit is related to the number of particles in the deposit (N) by $R_g \sim N^\delta$ ($\delta = 0.665 \pm 0.030$) in the limit of large N and long fibers. Consequently, deposits formed on fibers under diffusion-controlled conditions have fractal characteristics similar to

those associated with clusters formed under diffusion-controlled conditions. Similar but less quantitative results are presented for surface deposits. For two-dimensional deposits grown on a one-dimensional 'surface' under diffusion-controlled conditions, the root-mean-square thickness (T) of the deposit is related to the number of particles by $T \sim N^{\varepsilon}$ ($N \to \infty$). The exponent ε has the value 1.30±0.075. Similar results were obtained in three-dimensional simulations of diffusion-controlled deposition on a surface ($T \sim N^{\varepsilon}$, with $\varepsilon = 1.70 \pm 0.2$). All of the results reported in this paper were obtained using two- and three-dimensional lattice models. The results suggest that the structural characteristics of systems grown by diffusion-controlled processes are determined mainly by the dimensionality of the space in which the growth is occurring and are insensitive to geometric variables such as 'surface' curvature. 72286 Electronic structure factor of disordered materials. D.Belitz, A.Gold (Phys.-Dept., Tech. Univ. Munchen, Garching, Germany), W.Gotze, J.Metzger.
Phys. Rev. B (USA), vol.27, no.8, p.4559-63 (15 April 1983).
The dynamical structure factor of electrons in disordered systems is found to consist of two parts: One part is a disorder-induced elastic contribution with some form factor $S_e(\bar{q})$; the other one is related to the density relaxation spectrum. The authors evaluate $S_e(\bar{q})$ in perturbation theory and the density relaxation within the self-consistent current relaxation theory for two-and three-dimensional systems. For short-range potential fluctuations they find a peak in the static structure factor $S(\bar{Q})$ at $q \simeq 2k_F$. (18 refs.)

72287 Statistics of the levels in small metallic particles. K.B.Efetov (L.D. Landau Inst. of Theoretical Phys., Acad. of Sci., USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.467k-75 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.833-47 (Aug. 1982). [received: May 1983]
The problem of the computation of the two-level correlation function in a disordered metal is considered for the case in which the sample is of dimension much smaller than the diffusion length. The supersymmetry method, which allows the problem to be reduced to a problem of the zero-dimensional nonlinear σ model, is used. The symmetry of the collective variable is determined by the presence or absence of magnetic and spin-orbit interactions. It is shown that the correlation function depends on these interactions, and coincides in the various limits with the corresponding correlation functions obtained with the aid of Dyson's hypothesis for orthogonal, unitary, and symplectic ensembles. The computed correlation function determines the response to an external electromagnetic field. (15 refs.)

71.25 NONLOCALIZED SINGLE-PARTICLE ELECTRONIC STATES

72289 Theory of electronic structures and lattice distortions in polyacetylene and itinerant Peierls systems. III. Coulomb effects on solitons and effective Coulomb potential in trans-polyacetylene. H.Fukutome, M.Sasai (Dept. of Phys., Kyoto Univ., Kyoto, Japan).
Prog. Theor. Phys. (Japan), vol.69, no.2, p.373-95 (Feb. 1983).
For pt.II see ibid., vol.69, no.1, p.1-19 (1983). The authors study effects of the π electron Coulomb interaction on solitons in trans-polyacetylene utilizing the PPP Hamiltonian model developed in preceding papers of this series. Neutral soliton depends only on the on site and nearest neighbour parts of the effective Coulomb potential while charged solitons depend on its all parts. Owing to the Coulomb interaction, neutral soliton has a SDW like polarization cloud, while charged solitons have a CDW like one. The polarization clouds are consistent with ESR, ^{13}C NMR and XPS data. The formation energy of a zwitterionic pair of charged solitons, that gives the photoconductivity threshold, is very sensitively dependent on the strength and shape of the effective Coulomb potential. To get the observed small photoconductivity threshold, the effective Coulomb potential in trans-polyacetylene must have a screened long range part and about 50% screened on site and nearest neighbour parts compared to the one in small conjugate molecules. Such screening of the effective Coulomb potential is essential to make possible splitting of the ^1B_u exciton into a zwitterionic pair of charged solitons. (20 refs.)

72290 On the two-site spinless Falicov-Kimball model with hybridization. J.Zielinski, J.Kowalska (Inst. of Phys., Silesian Univ., Katowice, Poland).
Phys. Status Solidi b (Germany), vol.116, no.2, p.677-83 (1 April 1983).
The exactly solvable two-site extended Falicov-Kimball model is considered. It is shown that the increase of hopping energy lowers the tendency to an abrupt change of the average occupation number of f-electrons. Some thermodynamic quantities are evaluated. The results are used for the alloy analogy coherent potential approximation treatment of the periodic model. (22 refs.)

72291 Electronic states of doped semiconductors: a multiple scattering approach. A.Ghazali, J.Serre (Univ. Paris VIII, Paris, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.84-6 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The electronic structure of doped (and compensated) semiconductors is studied by using the Klauder's best multiple-scattering approximation. Electron correlations are also included. It is shown that as the impurity concentration is decreased, the band tail gradually splits off from the main band giving an impurity band. The domains of existence of extended states and localized states have been recognized by analyzing the shape of spectral densities. Lastly, compared results are compared with various experiments. (12 refs.)

72292 Generalized nonmuffin-tin band theory. R.G.Brown, M.Ciftan (Dept. of Phys., Duke Univ., Durham, NC, USA).
Phys. Rev. B (USA), vol.27, no.8, p.4564-79 (15 April 1983).
A new way of applying the nonspherically-symmetric phase-functional method of Williams and van Morgan (1974) to the band-structure problem is derived that results in a generalized (nonmuffin-tin) Green's-function band theory that is variationally stationary and exact in the single-electron, local-potential approximation. The 'near-field' correction, believed to destroy the separability of Green's-function band theories, is implicitly included in the nonspherically-symmetric phase-function basis. This basis is discused in some detail as the authors correct an error in the previous work of Williams and van Morgan. Using this basis to expand the crystal wave function, they obtain an equation that is the most general expression of Green's-function band theory. This equation contains a sum over the structure constants of the Korringa-Kohn-Rostoker method and two 'phase functions' (corresponding to the cosine and sine of the nondiagonal partial-wave shifts) that are independently calculable; hence the effects of structure and cellular potential completely separate. The variational procedure of Kohn and Rostoker then yields a secular determinant that can be solved for the nonmuffin-tin bands and wave functions; the resulting theory is suitable for self-consistent-field applications. 72293 XPS study of glassy $Pd_{80}Ge_{20}$. R.C.Budhani, A.Banerjee, T.C.Goel, K.L.Chopra (Dept. of Phys., Indian Inst. of Technol., New Delhi, India).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.93-102 (April 1983).
An X-ray photoemission and Auger electron spectroscopy study of the electronic structure of $Pd_{80}Ge_{20}$ alloy in its glassy and crystalline states is reported. The glassy state shows some modifications in the valence band structure, symmetry of the Pd $3d_{3/2}$-$3d_{5/2}$ spin-orbit doublet and a shift in M_{45}-V-V Auger transition of Pd. Analysis of the chemical shifts in the core-level binding energies of the constituents indicates negligible charge transfer from the metalloid atom (Ge) to d-band of the Pd. (29 refs.)

72294 Semiconductor-like structure of infinite linear polyacene. M.Baldo, G.Piccitto, R.Pucci, P.Tomasello (Dipartimento di Fisica, Univ. di Catania, Catania, Italy).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.201-3 (25 April 1983).
The authors investigate the Hartree-Fock ground state stability of linear polyacenes against spin-wave distortions. It is predicted that linear polyacenes with very many rings have an antiferromagnetic-like ground state and a semiconductor structure with a gap of about 1-2 eV. (19 refs.)

72295 Comments on the theory of amorphous semiconductors. M.H.Cohen (Corporate Res. Labs., Exxon Res. & Engng Co., Linden, NJ, USA).
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.125-37
Comments are made on the following: The nature of the intrinsic band tails in pure amorphous silicon, the Lloyd model, the influence of shallow impurity levels on band tails, the effect of disorder on deep levels, the question of whether excitons exist in amorphous semiconductors, the conductivity problem, the mobility edge problem, and optical absorption. New results are presented concerning the Lloyd model, shallow and deep impurity or defect levels, and excitons. In particular, the author concludes that excitons continue to exist as bound states only when the exciton lies below a Lifshitz limit, otherwise they survive only as resonance. (19 refs.)

72296 Electronic structure of Cu-Zr and PdSi metallic glasses. F.A.Leon, K.H.Johnson (Center for Materials Sci. & Engng., MIT, Cambridge, MA, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.193-7
The local electronic structures of representative amorphous alloys have been calculated using the SCF-Xα-SW cluster molecular orbital method. Prototype cluster models have been constructed for Cu-Zr and Pd-Si alloys which exemplify two major classes of binary (A-B) glass-forming systems, namely: (1) metallic glasses based on noble or transition elements (e.g. A=Cu) toward the right of the periodic table and transition elements (e.g. B=Zr) toward the left of the periodic table, (2) metalloid glasses based on transition elements (e.g., A=Pd) toward the middle of the periodic table and nonmetallic elements (e.g. B=Si) toward the right of the periodic table. The calculated electronic structures are in good quantitative agreement with, and provide an interpretation of, published photoelectron spectra for the above amorphous alloys. (12 refs.)

71.25P Band structure of crystalline metals

72297 Ligand field calculation of the relative displacements of the *d* band in V_3X system. Zhu Yuan-zhen, Pan Shao-hua (Inst. of Phys., Acad. Sinica, Beijing, China).
Acta Phys. Sin. (China), vol.32, no.3, p.411-16 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
By employing the method of ligand field theory, the authors calculated the additional potential energies of *d* electron states of V_3X (X=Si, Ga, Ge, Sb, Sn) superconducting compounds; these energies are induced by the D_{2d} crystal field. They obtained the analytic relation between the lattice constant and the relative displacement of *d* sublevels $\Delta E_\perp$, which is the characteristic quantity for the model of *d* band relative displacement. The numerical values of $\Delta E_\perp$ and the magnetic susceptibilities calculated by using them are also presented. (13 refs.)

72298 Electronic, superconducting, and optical properties of technetium from its augmented-plane-wave band structure. P.Chatterjee (Dept. of General Phys. & X-rays, Indian Association for the Cultivation of Sci., Jadavpur, Calcutta, India).
Phys. Rev. B (USA), vol.27, no.8, p.4722-8 (15 April 1983).
The detailed energy-band structure of hexagonal-close-packed technetium, corresponding to the atomic configuration $4d^55s^2$ of its seven outermost valence electrons, has been obtained throughout the Brillouin zone using the composite-wave variational version of the augmented-plane-wave (APW) method in conjunction with the $X\alpha$ (α=0.702 99) exchange approximation for obtaining the potentials. From the band-structure data the electronic density of states (DOS) and the angular-momentum-decomposed DOS were calculated by the accurate Gilat-Raubenheimer method (1967). These quantities were used to calculate the electron-phonon coupling constant and the transition temperature (T_c) using the theories of Gaspari and Gyorffy (1972) and of Mcmillan (1968). Also studied were the Fermi surface and the optical properties of Tc via the imaginary part of the interband dielectric constant for bound electrons, the latter being the first of such study on Tc to date. The superconducting properties and the Fermi surface which could be compared to experiments show, in general, satisfactory agreement. (32 refs.)

72299 Exchange banding of excited core states and its effects on core-level spectroscopies. H.S.Gotts (Dept. of Phys. & Astron., Univ. of Maryland, College Park, MD, USA), A.J.Glick.
Phys. Rev. B (USA), vol.27, no.8, p.4729-42 (15 April 1983).
The core levels of interest for soft-X-ray spectroscopies of the light metals are low-lying states with little overlap between states on neighboring ions. Consequently, it is usually assumed that the core level is very narrow and whatever width it has is due to lifetime and phonon broadening. However, when an electron is removed from a core state in a metal, a net transport mechanism appears other than direct tunnelling between sites. First-order exchange can carry a conduction electron into the core hole while an electron from another core site refills the conduction state. The net effect is the movement of the hole. This mechanism provides a first-order coupling between sites and results in the formation of an excited core-hole band. The authors discuss the spatial dependence and magnitude of the coupling between sites, the resulting band structure of the core level, and the implications of the banding on inner-shell spectra and their interpretation, particularly for the metals lithium and sodium. The calculated bandwidths range from ~8 to 25 meV for *K* levels and ~0.1 to 0.2 meV for the *L* levels (Na). Although the bandwidth (Li) is found to be of the same order of magnitude as the lifetime broadening, it affects the spectra in a very different way. Excited core states are now associated with a definite crystal momentum, and momentum is conserved in the transitions giving rise to the spectra. This selection rule serves to reduce the effect of the bandwidth on the (soft-) X-ray edge shapes. The bandwidths for Li and Na are shown to have little effect on the core-level spectra of these metals. (24 refs.)

71.25R Band structure of crystalline elemental semiconductors

72300 Bandwidth narrowing in n-type many-valley semiconductors. M.Fabbri, A.Ferreira da Silva (Inst. de Pesquisas Espaciais, Conselho Nacional de Desenvolvimento Cientifico e Tecnologico, Sao Jose dos Campos, Brazil).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.103-12 (April 1983).
A simple method that takes into account the many-valley effects of the host conduction band is outlined for the calculation of the impurity density of states. *N* random impurity sites were simulated with a computer, within a diamond lattice as a host. A Kohn-Luttinger donor wave function was associated with each impurity. It was found that the low energy side (or the high energy side when the effect of non-orthogonality is taken into account) of the density of states is strongly reduced to a small tail when compared to the case of neglecting many-valley effects. At the Fermi energy, the density of states is considerably enhanced which leads to an enhancement of the extrinsic specific heat. The inverse participation ratio varies with the impurity concentration, presenting different states which are responsible for different physical properties. An analytical calculation taking into account these effects was carried out for the sake of comparison. (14 refs.)

72301 The deformation potentials $\Xi\$_u^X$, Ξd^X of the X-valleys of the germanium conduction band. V.N.Ermakov, V.V.Kolomets, V.S.Timoshuk (Inst. of Semiconductors, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K77-8 (1 April 1983).
The authors show that using the results of Arisumi et al. (1969) where the value $\Xi_d^X+{}^1/_3\Xi_u^X$ was determined from I-U characteristics of a reverse-biased germanium tunnel diode at $\vec{P}\parallel[111]$ and the results of the authors paper (1979) on n-Ge piezoresistance at $\vec{P}\parallel[100]$ one may separately determine the values of the deformation potential constants. (4 refs.)

72302 Temperature dependence of the direct gap of Si and Ge. P.B.Allen (Dept. of Phys., State Univ. of New York, Stony Brook, NY, USA), M.Cardona.
Phys. Rev. B (USA), vol.27, no.8, p.4760-9 (15 April 1983).
The temperature dependences of the lowest direct gaps of germanium and silicon are calculated. They result from the effect of electron-phonon interaction on the corresponding electronic states. Both Debye-Waller (second-order interaction Hamiltonian) and 'self-energy' (first-order interaction Hamiltonian) are included. It is shown that the latter are by no means negligible. They reduce the calculated temperature coefficients at constant volume by a factor of 1.7 in the case of Si and 1.3 in the case of Ge. Agreement with experimental data is satisfactory. (22 refs.)

71.25T Band structure of crystalline semiconductor compounds and insulators

72303 On the conduction band edge energy of ice. D.Grand, A.Bernas (Phys. Chimie des Rayonnements, Univ. Paris-Sud, Orsay, France).
Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.119-22 (6 May 1983).
The conduction band edge energy V_0 of polycrystalline ice relative to vacuum has been estimated from the optical ionization potential I_{sol} of an impurity molecule A. Recording the stimulated recombination luminesence for A=indole leads to I_{sol}=5.55 eV and V_0=−0.1 eV, which is consistent with corresponding liquid-phase values. (21 refs.)

72304 Electronic structure of antiferromagnetic MnTe. M.Podgorny, J.Oleszkiewicz (Lab. Nazionali di Frascati, Istituto Nazionale Fisica Nucleare, Frascati, Italy).
J. Phys. C (GB), vol.16, no.13, p.2547-57 (10 May 1983).
The authors present a band calculation for antiferromagnetic MnTe. MnTe is found to be a semiconductor with an indirect energy gap of 0.35 eV. The

density of states and reflectivity spectra are presented and compared with experiment. As a result of comparison they conclude that optical properties of MnTe can be described in the framework of band theory. (35 refs.)

72305 Unusual behavior of Hg$_{1-x}$Cd$_x$Te and its explanation. W.E.Spicer, J.A.Silberman, P.Morgen, I.Lindau (Stanford Univ., Stanford, CA, USA), J.A.Wilson, An-Ban Chen, A.Sher.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.60-2 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The authors study the unusual semiconductor alloy, Hg$_{1-x}$Cd$_x$Te. They report the virtual crystal approximation (VCA) in that alloy (the first such breakdown in a semiconductor alloy), the success of the coherent potential approximation (CPA), the 'first order' explanation of these results in terms of energies of atomic valence levels, and the qualitative explanation of the unusual properties of Hg$_{1-x}$Cd$_x$Te in terms of the results reported above. Measurements were made with the use of photoemission spectroscopy. Cd and Hg core shifts are detected as a function of alloy composition and related to bonding concepts developed here. (12 refs.)

72306 Cyclotron resonance study of the conduction band in GaP. N.Miura, G.Kido, M.Suekane, S.Chikazumi (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.66-8 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Far-infrared cyclotron resonance was observed in n-type GaP at high magnetic fields in the megagauss range. For magnetic fields parallel to the ⟨100⟩ axis, the second absorption peak was observed at 100 T in addition to the first peak at 23T for a wavelength of 119 μm. The apparent cyclotron masses of electrons were thus determined to be $m^*_t=0.254\pm0.004$ m_0 and $m^*_l=4.8\pm0.5$ m_0 at 119 μm. At 337 μm, on the other band, a broad absorption band was observed around 42 T besides the first peak at 8.0 T. (10 refs.)

72307 Bonding nature of conduction states in electron-deficient semiconductors: Mg$_2$Si. F.Meloni (Istituto di Fisica, Univ. di Cagliari, Cagliari, Italy), E.Mooser, A.Baldereschi.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.72-4 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The electronic properties of Mg$_2$Si are calculated with the self-consistent pseudopotential method. The resulting energy bands agree with those of previous empirical pseudopotential calculations, are consistent with interband optical data, but are at variance with photoemission measurements since they predict the existence of a 3.5 eV intervalence energy gap. Analysis of the electronic charge distribution shows that the material is ionic with weak Mg-Si bonds. The first four conduction bands are formed from bonding molecular orbitals which extend throughout the unit cell. This surprising feature, probably common to other electron deficient semiconductors, is correlated to the low value of the energy gap in Mg$_2$Si, Mg$_2$Ge and Mg$_2$Sn. (17 refs.)

72308 'Two-hump' structure and parameters of the *X* minimum of the conduction band of cubic III-V semiconductors. A.A.Kopylov (V.I. Ulyanov Inst. of Electrical Engng., Leningrad, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1380-3 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2141-5 (Dec. 1982). [received: May 1983]
A theoretical determination is made of the parameters of the *X* minimum of the conduction band of cubic III-V semiconductors. It is shown that all III-V compounds, with the exception of AlP and InP, should have a two-hump structure of the X_1^c minimum, similar to that exhibited by GaP. A calculation is made of the temperature dependence of the density-of-states effective mass in the conduction band, which is due to the complex structure of the X_1^c minimum. (12 refs.)

71.30 METAL-INSULATOR TRANSITIONS

72309 Correlations and the metal-insulator transition. L.M.Sander (Phys. Dept., Univ. of Michigan, Ann Arbor, MI, USA).
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.115-24
Studies the model of Mott for a correlation-driven metal-insulator transition with particular emphasis on donors in semiconductors. The author considers donors with variable lattice spacing and finds the ground state energy, the magnetic properties, and the band structure. Modern techniques, notably the density-functional method, have led to detailed solutions. The author reproduces the Mott criterion ($n^{1/3}a_0=0.25$) for the metal-insulator transition which occurs at band crossing. His results agree with experiments for a wide variety of systems. The relationship to the Hubbard model is discussed. The results are useful even in a disordered system for predicting properties which are not sensitive to randomness, such as average band gap and dielectric enhancement. (22 refs.)

71.35 EXCITONS AND RELATED PHENOMENA

(inc. electron-hole drops)

72310 The vibration-quenching of the exciton and the Huang-Rhys factor in the quasi one-dimensional antiferromagnet CMC. Jia Wei-yi (Inst. of Phys., Acad. Sinica, Beijing, China), W.M.Yen.
Acta Phys. Sin. (China), vol.32, no.3, p.346-53 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
The exciton transition $^4T_1\rightarrow{}^6A_1$ of Mn$_n^{2+}$ ions in quasi one-dimensional antiferromagnet CsMnCl$_3$.2H$_2$O is very weak in intensity with a shorter lifetime due to the vibration-quenching. Replacing H$_2$O by D$_2$O, three important effects have been observed: the exciton line is shifted to the red by 18 cm^{-1}, the intensity of the exciton is increased by almost one order, the lifetime is lengthened from 0.58 ms to 9.2 ms. These facts show that the vibration-quenching has been weakened. The experimental results are analysed by means of the theory of multi-phonon radiative and non-radiative transitions. It has been shown that the isotope substitution changes the spectrum of lattice vibration, and brings forth a great influence on the non-radiative transition. The electron-phonon coupling intensity does not show any obvious change, and the Huang-Rhys factor remains constant. The phonon modes involved in the multi-phonon radiative transition are different from those involved in the multi-phonon nonradiative process, their average energies are quite different from each other. (12 refs.)

72311 Production of pairs of singlet excitons and triplet excitons in anthracene crystals. G.Klein (Lab. de Phys. des Rayonnements et d'Electronique Nucleaire, CRN, Strasbourg, France).
Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.114-18 (6 May 1983).
In anthracene crystals excited by high-energy photons (10-50 eV) there is enough to yield pairs of triplet excitons and singles excitons. The efficiencies of these processes are measured as a function of the incident photon energy. (16 refs.)

72312 The broadening of the kinematical exciton levels. G.S.Davidovic-Ristovski, L.M.Ristovski (Inst. of Phys., Faculty of Sci., Belgrade, Yugoslavia), B.S.Tosic, D.Mirjanic.
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.173-5 (25 April 1983).
The anomalous broadening of the exciton levels in a molecular crystal is explained as the broadening of the kinematical exciton levels, which are energetically close to the normal exciton levels. (7 refs.)

72313 Spin-lattice relaxation theory of excited triplet-state impurities in molecular crystals. V.I.Sugakov, Yu.D.Shtepa (Inst. for Nuclear Res., Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Status Solidi b (Germany), vol.116, no.2, p.633-8 (1 April 1983).
The processes of spin-lattice relaxation of the excited local triplet states in molecular crystals at low temperatures are investigated. The coupling of the translational and rotational motion of the molecule (TRC relaxation mechanism) is chosen as the major phenomenon, leading to the coupling of the spin system with acoustic vibrations. The general expressions for the spin-lattice relaxation time of the triplet centre in molecular crystal with impurities are derived taking into account the change of force constant due to the impurities. The angular, field, and temperature dependences of SLR time are calculated for an isotopic impurity in naphthalene crystal. The results of calculation are in accordance with available experimental data. (17 refs.)

72314 Effect of the pumping intensity on the resonant secondary emission spectra of optically aligned hot excitons in ZnTe crystals. M.Ya.Valakh, A.P.Litvinchuk, G.G.Tarasov (Inst. of Semiconductors, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K61-5 (1 April 1983).
The band-to-band excitation of semiconductors by polarized laser radiation produces polarized secondary emission and its polarization provides information on the energy relaxation of optically aligned hot carriers or excitons. Investigations of the degree of polarization versus the excitation frequency and the number of LO-phonons emitted during the relaxation process have been carried out previously in order to study possible relaxation mechanisms. The authors show that investigations of the effect of excitation intensity on the secondary emission spectra give an important additional information. (6 refs.)

72315 Phase transitions in electron-hole liquids. P.Nozieres (Inst. Laue-Langevin, Grenoble, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.16-22 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The equilibrium thermodynamics of electron-hole gases in semiconductors are reviewed, especially the problems of metal-insulator transitions and Bose Einstein condensations. (28 refs.)

72316 Symmetry breaking excitonic instabilities in deformable lattice. Y.Toyozawa (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.23-9 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Three types of symmetry-breaking instabilities of exciton(s) in the phonon field are described on a unified view-point and in comparison with relevant observations. (i) Self-trapping—broken translational symmetry—takes place when the exciton-lattice relaxation energy exceeds the exciton kinetic energy for localization. (ii) Decomposition into a pair of self-trapped particles—broken parity—may arise when the electron and the hole have deformation potentials of opposite sign. (iii) If the total lattice relaxation energy exceeds the Franck-Condon exciton energy, the relaxed electron-hole pairs spontaneously created everywhere will condense into a new ordered state—bulk phase change. (40 refs.)

72317 Symmetry-breaking effect on N-bound excitons in GaP. J.Camassel, H.Mathieu (Centre d'Etudes d'Electronique des Solides, Univ. Sci. et Technol. du Languedoc, Montpellier, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.96-101 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
A review of experimental data obtained on N-bound excitons under application of a uniaxial stress is given. This includes: single excitons bound to single nitrogen atoms, excitonic molecules bound to single nitrogen atoms and, lastly, single excitons bound to pairs of nitrogen atoms. (16 refs.)

72318 Shallow isoelectronic excitons revisited. C.Benoit a la Guillaume (Univ. de Paris VII, Paris, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.105-7 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
A simple model of isoelectronic exciton is solved in the Hartree selfconsistent method. It shows how the usual Hopfield, Thomas, Lynch model is modified for very small binding. It explains well the excitation spectrum of excitons bound to NN pairs in GaP. A new calculation of the energy of NN_i^- is presented, which proves unambiguously that the N^- state in GaP is unstable. (7 refs.)

72319 Excitation spectroscopy in silicon: pseudo-acceptor excited states of the isoelectronic A, B, C exciton system. J.Wagner (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany), R.Sauer.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.113-15 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The authors perform excitation spectroscopy with a tunable $NaF:(F_2^+)^*$ color center laser on the isoelectronic A, B, C exciton system in silicon and detect seven highly excited states. They are interpreted in terms of excited hole states of a pseudo-acceptor split in the axially symmetric field of the binding center. The hole states fit excellently into the systematics of common acceptor spectra in silicon when the pseudo-acceptor ionization energy is chosen as 36.7 meV. (11 refs.)

72320 Theoretical and experimental aspects of the nonlinear spectroscopy of biexcitons in CuCl. I.Abram, A.Maruani, D.S.Chemla, F.Bonnouvrier, E.Batifol (CNET, Bagneux, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.301-2 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Forward degenerate fourwave mixing in CuCl in the vicinity of the two-photon absorption on the biexciton can be analyzed from two complementary theoretical points of view: (a) In terms of the traditional perturbational formulation of nonlinear optics, the low intensity observations can be accounted for in terms of interferences and re-normalizations among different-order elementary mixing processes; (b) In terms of a perturbational scheme which provides directly an analytic expression for the intensity-dependent dielectric function of the material. This last approach points to a potentially bistable optical response when local field effects are included in the calculation. (6 refs.)

72321 Non-equilibrium exciton phase in the high density regime of a direct-gap semiconductor. G.W.Fehrenbach, W.Schafer, J.Treusch, R.G.Ulbrich (Inst. fur Phys., Univ. Dortmund, Dortmund, Germany).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.303-5 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The 1s-exciton absorption of GaAs is measured under conditions of fast transient resonant excitation with laser pulses of 8 psec duration and 1.2 meV bandwidth centered on the 1s-exciton line. The 1s-exciton remains stable up to pair densities exceeding the Mott density by more than an order of magnitude. This remarkable persistence is due to the resonant excitation mechanism: the existence of a gap between the externally excited 1s exciton state and free electron-hole pair states leads to a strong reduction of screening in comparison with plasma screening through mobile carriers. (6 refs.)

72322 Electron-hole liquid condensation: systematics and scaling relations. T.L.Reinecke (Naval Res. Lab., Washington, DC, USA), A.Forchel, H.Schweizer, B.Laurich, A.Hangleiter, J.Wagner, W.Schmid.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.315-17 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Studies of electron-hole liquid (EHL) condensation in Si, in several strained Si systems, in strained Ge, and in GaP are reported, and they provide the most extensive results to date for the systematic variations with band structure of the ground state and critical properties of EHL. The ground state densities of these systems vary by a factor $\sim 10^3$ and the critical temperatures by a factor ~2O. Investigations of Si with varying magnitudes of uniaxial strains provide the first systematic data for systems with significant band non-parabolicities. Based on these results proposals for scaling relations between the ground state properties and the critical points are tested, and a recently proposed set is verified in quantitative detail. (9 refs.)

72323 Interaction of phonons with the electron-hole liquid. J.P.Wolfe (Phys. Dept., Univ. of Illinois, Urbana, IL, USA).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.321-6 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Three new experiments are described which quantify the interaction of high-frequency phonons with the electron-hole liquid. Drift measurements in Si have determined the mobility of electron-hole droplets (EHD) and shown a temperature dependence of the electron-phonon scattering rate which is characteristic of a degenerate Fermi fluid. The drift velocity of EHD strongly saturates at near-sonic velocities, suggesting a Cherenkov-like phonon emission. Phonon spectroscopy in the 150-500 GHz range has determined the dynamic deformation potential and demonstrated the predicted $2k_F$-cutoff in the absorption of phonons by EHD in Ge. Time-resolved luminescence imaging has revealed an interesting phonon-wind-induced anisotropy in a cloud of electron-hole droplets which is produced by intense pulsed-laser excitation of Ge. (22 refs.)

72324 Spin aligned exciton gas in uniaxially compressed Ge. V.B.Timofeev, V.D.Kulakovskii, I.V.Kukushkin (Inst. of Solid State Phys., Acad. of Sci., Chernogolovka, USSR).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.327-32 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Demonstrates a unique opportunity for investigation of the statistical behaviour of a spin aligned exciton gas up to high densities corresponding to $r_s \approx 2$ at $T \approx 2K$ in strongly uniaxially compressed Ge in a magnetic field. The experimentally observed changes in the exciton-phonon emission spectra of a dense exciton gas are interpreted in terms of the weakly nonideal Bose-gas. The ionization collapse (Mott transition) of excitons giving rise to an abrupt change in electron transport phenomena has been observed at density corresponding to $r_s = 2$. (21 refs.)

72325 Theoretical and experimental studies of the transition from the exciton to the plasma phase. S.Schmitt-Rink (Inst. fur Theoretische Phys., Univ. Frankfurt, Frankfurt, Germany), J.P.Lowenau, H.Haug, K.Bohnert, A.Kreissl, K.Kempf, C.Klingshirn.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.339-41 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The complex dielectric function of a semiconductor is calculated for an arbitrary number of free carriers. Large dispersive changes occur when the exciton is ionized due to an increased screening of the Coulomb potential. The intensity-dependent changes of the refraction and absorption spectra are measured directly from the shifts to the eigenmodes of a CdS platelet resonator. (5 refs.)

72326 Eigenstates of *N* excitons and one hole. R.Schilling, D.C.Mattis (Phys. Dept., Univ. of Utah, Salt Lake City, UT, USA).
Phys. Rev. B (USA), vol.27, no.8, p.4661-4 (15 April 1983).
The authors solve for the eigenstates and energy eigenvalues of N immobile Frenkel excitons (a relatively trivial proposition) and of N such excitons plus one hole (which for large N can only be done in one dimension). They also guess that a charged globule, consisting of N excitons and $O(N)$ holes, can be stable, if, in any number of dimensions, m_h^* for holes is much larger than m_e^* for electrons. (8 refs.)

72327 The Brewster effect in exciton reflectance spectra. A.B.Pevtsov, A.V.Sel'kin (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.282-90 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.516-31 (Aug. 1982). [received: May 1983]
The conditions under which the Brewster effect manifests itself in exciton oblique-reflectance spectra are considered for the first time. It is shown that, in the isolated-exciton-resonance model that takes account of the spatial dispersion and the presence on the crystal surface of an exciton-free homogeneous dielectric layer, the reflectance can vanish completely for either the *p*-or *s*-polarized component within the limits of the exciton reflectance band. The amplitude-phase spectral dependence of the reflectance has been experimentally investigated for the crystals ZnTe, ZnP_2 ($T=2K$), and CdS ($T=2$ and 77K) in the case of oblique incidence of the light in the region of the lowest exciton resonances. The results show that the exciton Brewster effect occurs in all these crystals (in the case of ZnP_2 it manifests itself in the *s*-polarized component). The theoretical model satisfactorily describes the experimental data. (23 refs.)

72328 Low-energy surface exciton impurity states. V.N.Ermakov, O.Yu.Mikityuk, V.V.Nitsovich.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.534-7 (April 1983). In Russian.
Localization of surface excitons on impurities with small effective charges is investigated. An equation of state is derived in the T-matrix approximation for the surface impurity-bound exciton. An oscillator force is calculated for the exciton transition to localized surface exciton-impurity states with low binding energy. (7 refs.)

(inc. photon-phonon and photon-magnon interactions)

72329 Determination of additional boundary conditions in CuCl [excitonic polaritons]. Y.Segawa, Y.Aoyagi, S.Komuro, S.Namba (Inst. of Phys. & Chem. Res., Saitama, Japan), S.Inoue, M.Nakayama.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.309-11 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Two induced absorption lines from the upper and the lower branch excitonic polaritons to the excitonic molecule were observed in CuCl near the longitudinal exciton. The intensity of the induced absorption from the lower branch polariton decreases gradually with the increase of the energy at the high energy side of the longitudinal exciton. The oblique incidence reflection spec-

tra were also observed for the same sample. A sharp structure appears in the p wave reflection spectrum. A new theory of additional boundary conditions by a model for the surface scattering of the polariton can fairly well explain the observed results. (5 refs.)

71.38 POLARONS AND ELECTRON-PHONON INTERACTIONS

(for electron-phonon interactions in lattices, see also 63.20K)

72330 The bound one-dimensional ‘relativistic’ polaron in a one-loop approximation. A.A.Bytsenko, S.A.Ktitorov (A.F. Ioffe Phys.-Tech. Inst., Acad. of Sci, Leningrad, USSR).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.316-18 (9 May 1983).
A quasirelativistic model of the narrow-gap semiconductor is considered. The interaction of the Dirac electron field with the nondispersive phonon field in the short-range external potential (impurity) is taken into account. The classical solutions corresponding to the discrete spectrum are found. The fermion vacuum polarization effect is studied within the one-loop approximation. (7 refs.)

72331 AsF$_5$-doped polyparaphenylene: evidence for polaron and bipolaron formation. G.Crecelius, M.Stamm (Inst. fur Festkorperforschung der Kernforschungsanlage, Julich, Germany), J.Fink, J.J.Ritsko.
Phys. Rev. Lett. (USA), vol.50, no.19, p.1498-1500 (9 May 1983).
Both elastic and inelastic electron scattering have been used to characterize and investigate the electronic properties of AsF$_5$-doped polyparaphenylene. Evidence is presented for the existence of a polaron state slightly above the top of the valence band at low doping levels. An increase in the doping level first leads to the formation of bipolaron states which broaden and finally form a band in the gap in agreement with recent theoretical predictions. (7 refs.)

72332 Many electron magnetic polaron in magnetic semiconductors. J.Sinkkonen, P.Kuivalainen (Dept. of Electrical Engng., Helsinki Univ. of Technol., Espoo, Finland).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K73-6 (1 April 1983).
The authors study the few electron polaron within a simple potential well model. They take into account the positive background of the crystal, i.e. the space charge layer formed by ionized donors which surround the autolocalized cluster of conduction electrons. This effect, which was neglected by Kasuya (1976), allows them to study, e.g. the molecular magnetic polaron (MMP) stability as a function of doping concentration. (7 refs.)

72333 Direct path-integral treatment of the polaron problem. A.L.Kholodenko, K.F.Freed (James Franck Inst., Univ. of Chicago, Chicago, IL, USA).
Phys. Rev. B (USA), vol.27, no.8, p.4586-600 (15 April 1983).
Direct evaluation of Feynman's functional integral for the polaron maps it into a standard type of many-body theory. The perturbation expansion is shown to be well controlled and does not require any renormalization. This perturbation expansion has the pleasing feature that nth-order terms in the polaron coupling constant are obtained from nth-order perturbation theory, whereas the traditional perturbation formulation in terms of creation and annihilation operators requires a 2nth-order perturbation calculation to generate the same results. In contrast to previous beliefs, the method is shown to enable the calculation of the polaron effective mass and relaxation time directly from the functional-integral expression. The ground-state energy is computed to second order in the polaron coupling constant to illustrate the use of the method and to establish agreement with previous perturbation treatments. In addition, the authors provide the first perturbation calculation of the polaron effective mass through second order in the coupling constant. Pade approximants are shown to provide a vehicle for analytically extending the perturbation results into the region of intermediate and strong couplings, and the procedure yields reasonable agreement with variational calculations for values of the polaron coupling constant up to about $\alpha=10$. In addition, conditions are derived under which the original polaron action, used in the functional integral, reduces to some of the best variational trial actions utilized in the literature. (37 refs.)

72334 The effect of anharmonism and dispersion on Davydov soliton properties. N.I.Kislukha, A.V.Karbovskii.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.515-20 (April 1983). In Russian.
Properties of the Davydov soliton at velocities close to the limiting velocity of longitudinal sound waves are considered with effect of anharmonism and the mutual effect of anharmonism and the dispersion of sound waves in a molecular chain. For solitons whose energy is lower than the excitation band bottom and which satisfy the applicability condition of the continual approximation, the anharmonism effect appears to dominate and the presence of sound dispersion is reduced. (3 refs.)

71.45 COLLECTIVE EFFECTS

72335 Anomalous quantum Hall effect: an incompressible quantum fluid with fractionally charged excitations. R.B.Laughlin (Lawrence Livermore Nat. Lab., Univ. of California, Livermore, CA, USA).
Phys. Rev. Lett. (USA), vol.50, no.18, p.1395-8 (2 May 1983).
Presents variational ground-state and excited-state wave functions which describe the condensation of a two-dimensional electron gas into a new state of matter. (8 refs.)

72336 Connection between the heat capacity and the effective mass of the electrons in Fermi-liquid theory at finite temperatures. G.O.Zaiitsev (Moscow State Extension Pedagogical Inst., Moscow, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.331-3 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.601-6 (Aug. 1982). [received: May 1983]
The effect of electron-phonon interaction on the connection between the electronic heat capacity and the effective mass of the electrons in metals is investigated. It is shown that this connection is essentially nonlocal and is independent of the phonon spectrum $g(\omega)=\alpha^2(\omega)F(\omega)$. A simple differential relation is obtained between the heat capacity of the electrons in a metal and the known Fermi-liquid formula for the heat capacity of electrons. (6 refs.)

71.45G Exchange, correlation, dielectric and magnetic functions, plasmons

72337 The total dielectric screening effect in III-V and II-VI compounds. M.Grinberg (Dept. of Phys., Warsaw Tech. Univ., Plock, Poland), S.Legowski, H.Meczynska.
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.485-95 (April 1983).
The total spatial dielectric functions and the wave-vector-dependent dielectric functions for III-V and II-VI compound semiconductors CdTe, GaAs are obtained for a model which includes the anharmonicity of the lattice. It has been pointed out that the ionization donor energies are slightly affected by the anharmonicity. Therefore in the investigated compounds the scaling procedure of the electronic dielectric function is justified. (21 refs.)

72338 Amplification of two-dimensional plasma waves by a charged-particle beam. N.N.Beletskii, S.N.Khar'kovskii, V.M.Yakovenko (Sci.-Res. Inst. of Radiophys. & Electronics, Acad. of Sci., Kharkov, Ukrainian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1409-10 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2182-5 (Dec. 1982). [received: May 1983]
The authors describe a method of generating surface plasmons in a two-dimensional electron gas by a steam of charged particles incident normally on its surface. Then, in contrast to the case of parallel motion, the relationship between the velocity of a beam and the phase velocity of waves can be arbitrary. Moreover, the thickness of a two-dimensional layer is then so small that the layer is in fact transparent to a charged-particle beam. (7 refs.)

71.45N Calculations of total electronic binding energy

(see also 61.50L Crystal binding)

72339 Diatomic molecules and metallic adhesion, cohesion, and chemisorption: a single binding-energy relation. J.Ferrante (NASA, Lewis Res. Center, Cleveland, OH, USA), J.R.Smith, J.H.Rose.
Phys. Rev. Lett. (USA), vol.50, no.18, p.1385-6 (2 May 1983).
It has been discovered that a single relation between binding energy and interatomic spacing can describe the energetics of diatomic molecules, bulk metals, bimetallic interfaces, and gas atom-metal surface interactions. (7 refs.)

71.50 LOCALIZED SINGLE-PARTICLE ELECTRONIC STATES

(exc. impurities; for localisation in disordered structures, see 71.55J)

72340 Localization redux. P.W.Anderson (Bell Labs., Murray Hill, NJ, USA).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.30-5 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The author surveys recent progress in the field of localization. Theory and experiment are in excellent agreement in two-dimensional systems such as inversion layers and thin metal films. The metal insulator transition in three-dimensional systems remains an interesting problem as exemplified by highly accurate data on doped semiconductors, but on the metallic side perturbational theory has had a number of successes. (39 refs.)

72341 Localization and correlation effects in metals and semiconductors—experiment. R.C.Dynes (Bell Labs., Murray Hill, NJ, USA).
Melting, Localization, and Chaos. Proceedings of the Ninth Midwest Solid State Theory Symposium, Argonne, IL, USA, 2-3 Nov. 1981 (New York, USA: North-Holland 1982), p.139-52
The current experimental situation with respect to electron localization and the metal-insulator transition is reviewed. Attempts to study the phenomena in one, two and three dimensions are outlined. One dimensional effects have been clearly observed, but at the moment the length scale remains a mystery and it is difficult to separate localization effects from many-body correlations. In two dimensions, magnetoresistance, Hall effect and temperature dependent resistivity measurements allow a measure of the relative strengths of these two effects, and illustrate remaining problems. In three dimensions, various systems studied illustrate strong correlation effects and apparent differences. The nature of the transition remains elusive. (41 refs.)

71.55 IMPURITY AND DEFECT LEVELS

72342 A tight-binding model of the oxygen-vacancy in $SrTiO_3$. M.O.Selme, P.Pecheur (Lab. de Phys. du Solide, ENSMIM, Nancy, France).
J. Phys. C (GB), vol.16, no.13, p.2559-68 (10 May 1983).
Using a tight-binding parameterisation of the band structure of $SrTiO_3$ together with the Green functions method, the authors calculate the energy levels of the oxygen vacancy. They show the ionic character of this defect and compare their results with previous calculation and experiments. They suggest an instability of the neutral and singly ionised vacancy with respect to polaron formation. (21 refs.)

72343 Electronic states of *F*-type centers in oxide crystals: a new picture. S.-il.Choi (Dept. of Phys. & Astron., Univ. of North Carolina, Chapel Hill, NC, USA), T.Takeuchi.
Phys. Rev. Lett. (USA), vol.50, no.19, p.1474-7 (9 May 1983).
A strong case is made to show that the *F*-type color centers in oxide crystals are qualitatively different from the color centers of alkali halides. A semi-quantitative discussion is followed by the results of an $X\alpha$ self-consistent-field calculation for the α-Al_2O_3 crystal. An oxygen-ion vacancy in α-ilumina is a deep electron trap, the ground state of which lies between the two valence bands, unlike the *F* center of alkali halides whose ground state lies between the valence and conduction bands. The two electrons in the trap are stabilized by a hole. (16 refs.)

72344 Structure of muons trapped in aluminium. B.I.Craig (Dept. of Phys., Univ. of Newcastle, Newcastle, NSW, Australia).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K91-4 (1 April 1983).
The author uses the aluminium-hydrogen system to investigate the trapping of muons in aluminium. A point positive charge $+e$ is assumed to describe the proton. A highly localised wave function for the interstitial has therefore been assumed. The resulting electronic structure is obtained through the calculation of the change in the metal valence electron charge density $\Delta\rho(\bar{r})$. (6 refs.)

72345 Electrical properties of donors in gallium phosphide. B.Podor (Res. Lab. for Inorganic Chem., Hungarian Acad. of Sci., Budapest, Hungary).
Phys. Status Solidi a (Germany), vol.76, no.2, p.695-704 (16 April 1983).
The thermal ionization energies of S, Te, and Si donors in GaP and their dependences on impurity concentration are determined from an analysis of Hall effect data. An ellipsoidal six-valley model is used incorporating the effects of valley-orbit splitting of the ground state of the P-site donors. A careful characterization of the samples ensures that results are obtained on samples containing only one type of dominant donor. The thermal ionization energies of the above donors extrapolated to infinite dilution are (105.0 ± 5.7), (94.1 ± 2.6), and (83.5 ± 1.7) meV, respectively. The valley-orbit splitting energies of S and Te donors are also obtained, amounting to (34 ± 9) and (23.5 ± 9) meV, respectively. (33 refs.)

72346 Deep levels in semiconductors. G.D.Watkins (Dept. of Phys., Lehigh Univ., Bethlehem, PA, USA).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.9-15 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The 3d transition element ion impurities in silicon are reviewed for the broad insight they provide in understanding deep levels in semiconductors. As interstitials, their interaction with the host tends to confine the d-levels to the forbidden gap, providing many deep states. The interaction at the substitutional site is best considered as an interaction with the lattice vacancy, into which the impurity is placed. This interaction tends to repel deep a_1 and t_2 levels from the gap. When the levels are present, they are mostly vacancy-like and the defect is likely to display the large lattice relaxations characteristic of the vacancy. (31 refs.)

72347 Far-infrared studies of the bound and free carriers in n-InSb as a function of hydrostatic pressure. Z.Wasilewski (Phys. Dept., Univ. of St. Andrews, St. Andrews, Scotland), A.M.Davidson, R.A.Stradling.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.89-91 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Magneto-optical studies are presented of the interaction between Γ and L-associated donor states. The admixture of L-states permits intervalley coupling by a single TA(L) phonon of energy of 35 cm^{-1}. When metastable states of predominantly X-character are occupied, L-like transitions involving the same donor disappear. (12 refs.)

72348 Metastable donor states in Te-doped $Ga_{1-x}Al_xSb$ compounds. L.Konczewicz, E.Litwin-Staszewska, S.Porowski, A.Iller (High Pressure Res. Center 'Unipress', Polish Acad. of Sci., Warsaw, Poland), R.L.Aulombard, J.L.Robert, A.Joullie.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.92-5 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
On highly doped (Te) n-type bulk crystals of $Ga_{1-x}Al_xSb$ ($x\leq0.3$) the Hall coefficient and resistivity have been measured as a function of temperature in the range 77K-300K and pressure up to 1500 MPa. It was found that the pressure induced strong decrease of L-minimum conductivity is connected with deionization of Te-donor impurity. It is characterized by two states E_d and E_s with different pressure coefficients: $dE_d/dp=4.9\ 10^{-5}$ eV/MPa; $dE_s/dp=1.2\ 10^{-6}$ eV/MPa. The metastable nature of this state was observed and from the analysis of $R_H(t)$ dependences the value of the potential barrier which controls the capture of electrons was determined to be equal to 0.26 eV. At 77K the presistent photoconductivity was observed and optical ionization energy was estimated to be equal 1 eV. (13 refs.)

72349 Electron and positron response to atomic defects in solids: A theoretical study of the monovacancy and divacancy in aluminum. B.Chakraborty, R.W.Siegel (Materials Sci. & Technol. Div., Argonne Nat. Lab., Argonne, IL, USA).
Phys. Rev. B (USA), vol.27, no.8, p.4535-52 (15 April 1983).
A formalism for self-consistently calculating the response of electrons and positrons to atom defects in solids is presented. The formalism can be used with either the Green's function or supercell method for calculating defect characteristics, and is of general applicability. With the use of this formalism and the self-consistent pseudopotential scheme within a supercell, the electronic structure and positron states and annihilation characteristics associated with the monovacancy and divacancy in aluminum have been studied. The sensitivity of the calculated monovacancy electronic structure and formation energy to the type of ionic pseudopotential used is also examined. Finally, the possibilities for using positron-annihilation spectroscopy to study the electronic structure of vacancylike defects are considered. (35 refs.)

72350 The wave function of impurity states and its pressure dependence. J.Krupski (Inst. of Theoretical Phys., Warsaw Univ., Warsaw, Poland), W.Trzeciakowski.
Solid State Commun. (USA), vol.46, no.4, p.283-6 (April 1983).
The authors calculated the wave function of the ground state of an impurity which introduces into the crystal both Coulomb and short-range potential. The probability of finding an electron at the impurity site and the optical matrix elements for the transitions from the ground state to the excited states were found and their dependence on the hydrostatic pressure was discussed. (5 refs.)

72351 A note on the pressure dependence of the EL2 level in gallium arsenide. P.Dzwig (Cavendish Lab., Cambridge Univ., Cambridge, England).
Solid State Commun. (USA), vol.46, no.4, p.305-7 (April 1983).
Various experiments involving the application of hydrostatic pressure and uniaxial stress to the EL2 level in gallium arsenide are compared with a 4×4 impurity superlattice model. This is used to study the pressure dependence of the unoccupied level and verifies that it does indeed follow the conduction band edge as observed in photocapacitance. It also supports the view that hte separation from the conduction band with pressure of EL2 observed in transient capacitance is due in large part to the pressure dependence of the Franck-Condon shift. It is noted that as compared with $Ga_{1-x}Al_xAs$ in the appropriate range of x, the variation of the level with pressure is approximately correct and that it would seem that the frequently made analogy between alloying and pressure dependence is justified here. (10 refs.)

72352 Energy spectrum of Sn and Ge impurity states in solid solutions based on lead chalcogenides. L.V.Prokof'eva, S.V.Zarubo, M.N.Vinogradova, Yu.A.Nikulin, K.G.Gartsman (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1377-9 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2136-40 (Dec. 1982). [received: May 1983]
The Hall and other transport coefficients were determined in a study of the energy position of the band of *s* states of Sn and Ge in solid solutions based on lead chalcogenides. This position was determined as a function of the solid-solution composition and of temperature. The temperature dependence of the energy impurity states was determined by the role performed by the impurity level in question, interacting with the valence band. At low temperatures *T* an impurity level whose occupancy differed from 0 and 1 was a donor and an increase in *T* shifted the level upward toward the edge of the valence band. At high temperatures *T* an impurity level acted as an acceptor and its temperature-induced shift was in the opposite direction. The nonmonotonic temperature dependences of the energies of the Sn and Ge impurity states were interpreted using a model according to which impurity sites with different charges occupied at low temperatures inequivalent positions in the lattice and, consequently, the occupied and free states of an impurity corresponded to different energies. An increase in *T* reduced the inequivalence of the sites with different charges and at some temperature, which was a function of the composition, this difference disappeared. (6 refs.)

72353 Photoionization of deep impurity centers in semiconductors doped with transition elements. V.I.Kirillov, D.I.Materikin, S.I.Rembeza (Polytech. Inst., Voronezh, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1415-16 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2190-2 (Dec. 1982). [received: May 1983]
The authors calculate the photoionization cross section of deep centers whose ground state has a nonzero orbital quantum number *l*. They consider the case of transition element doped semiconductors where the not only potential scattering but also resonance scattering of a *l*-th partial Bloch wave by a d impurity occurs. (11 refs.)

72354 Experimental determination of the characteristics of deep centers in III-V crystals on the basis of a two-band model. N.M.Kolchanova, M.A.Sipovskaya, Yu.S.Smetannikova (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1418-19 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2194-6 (Dec. 1982). [received: May 1983]
The authors report the results of a comparison of the calculated dependences of the photoionization cross sections $\sigma=f(\hbar\omega)$ with the experimental data for a center in GaAs characterized by an ionization energy $\epsilon_i=0.75$ eV and a center with $\epsilon_t=E_v+0.13$ eV in InSb. An analysis shows that the ϵ_i center in GaAs is a donor of the *l*-c type with the Γ_6 symmetry, whereas the ϵ_t center in InSb is a donor center of the h type and with the Γ_8 symmetry. They investigated the impurity photoconductivity of high-resistivity GaAs in the photon energy range 0.6-1.5 eV. The activation energy of the deep level ϵ_i was 0.75 eV. (8 refs.)

71.55J Localization in disordered structures

72355 Reversible photoinduced modification of electron-capture cross section at localized states in *a*-Si:H. H.Okushi, M.Miyagawa, Y.Tokumaru, S.Yamasaki, H.Oheda, K.Tanaka (Electrotech. Lab., Ibaraki, Japan).
Appl. Phys. Lett. (USA), vol.42, no.10, p.985-7 (15 May 1983).
A reversible photoinduced modification of the electron-capture cross section at localized states in P-doped *a*-Si:H has been directly observed, being associated with the Staebler-Wronski effect. Isothermal capacitance transient spectroscopy measurement shows that the electron-capture cross section at the gap states located at around 0.5 eV below the conduction-band mobility edge (E_c) increases after the band-gap illumination and is nearly stored to its original value by thermal annealing below 200°C. It has been suggested that a metastable state related with the dangling bond is created through the multiphoton emission when excess carriers recombine. (16 refs.)

72356 Gap states in a-Si:H by photoconductivity and absorption. F.Evangelisti, P.Fiorini, G.Fortunato, A.Frova, C.Giovannella, R.Peruzzi (Istituto di Fisica 'G. Marconi', Univ. di Roma, Rome, Italy).
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.191-201 (May 1983).
The spectral dependence of photoconductivity in a series of a-Si:H samples has been analyzed in order to derive the absorption coefficient α. It has been found that the exponent β which relates photoconductivity and generation rate varies with photon energy and chopping frequency. Its critical influence upon the value of α is established. The Urbach tail in the region 1.4-1.8 eV has been studied and found to be independent of extrinsic gap states and hydrogen content. Finally an inverse correlation has been determined between the photoconductivity lifetime and the extrinsic gap-state density, as measured from the corresponding integrated area of the absorption coefficient. (14 refs.)

72357 Experimental tests of localization in semiconductors. G.A.Thomas (Bell Labs., Murray Hill, NJ, USA).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.81-3 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The characteristic lengths of the electron wave function in a random three-dimensional system tend to diverge at a critical point at zero temperature and a density n_c. The results differ from predictions of Mott (1972, 1981) and of scaling theories of localization. The lengths associated with electron diffusion appear to be dominated by Coulomb interactions and electron-electron inelastic scattering. (15 refs.)

72358 Density of states and critical resistivity of strongly disordered systems. K.A.Muttalib (James Franck Inst., Univ. of Chicago, Chicago, IL, USA).
Phys. Rev. B (USA), vol.27, no.8, p.4628-31 (15 April 1983).
Recently the author proposed that the anomalous diffusion at short length scales associated with localization is responsible for the unusual sensitivity of the high-T_c superconductors to disorder. It was shown that the Coulomb pseudopotential in superconductors is a universal function of ρ/ρ_c, where ρ is the resistivity and ρ_c is a critical resistivity characteristic of the system, and obtained relatively small values of ρ_c from the experimental T_c vs. ρ curves. In the present paper the author shows that the strong-disorder region in three dimensions the density of states is also a universal function of the same parameter, so that in the absence of any microscopic calculation of ρ_c, a comparison of the density of states and T_c as function of disorder provides a crucial test of the theory. Very good agreement is found with existing data on granular Al. The density of states has a logarithmic energy dependence in this region, a result independently obtained by Lee (1982). In addition, the author makes quantitative predictions about where and when to expect this logarithmic correction to be important, and comments on why it has not been observed yet. (7 refs.)

72359 The absorption spectrum of d^2 ions in a trigonally distorted cubic crystal field. Ma Dong-ping, Hu Zhi-xiong, Xu Yi-sun (Chengdu Inst. of Agricultural Machinery, Pi Xian, China).
Acta Phys. Sin. (China), vol.32, no.3, p.366-75 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
By using the irreducible tensor operator method, two corollaries have been derived from generalized Wigner-Eckart theorem and the results associated with the corollaries are obtained. For the d^2 ions in a trigonally distorted cubic crystal field, the effective method dealing with overall problems of D, $g_\parallel$, $g_\perp$ and absorption spectrum has been suggested on the basis of unified model, in which all possible interaction of V_c and $(V_{tr}+H_s)$ have been considered. In application to vanadium corundum, successful results in agreement with the experiments are obtained by overall fitting of the theoretical values to the observed values of D, $g_\parallel$, $g_\perp$ and absorption spectrum. (14 refs.)

72360 Pseudo Jahn-Teller effect and distortion isomers of $CuBr_2(NH_3)_2$ crystals. T.Obert (Dept. of Chem. & Tech. Phys., Slovak Tech. Univ., Bratislava, Czechoslovakia), I.B.Bersuker.
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.5, p.568-73 (1983).
Relation of the values characteristic of pseudo Jahn-Teller effect to values which are characteristic of distortion isomerism of $CuBr_2(NH_3)_2$ coordination compound has been found. It follows from the results of this work that it is possible to explain the distortion isomerism of the compound mentioned before as a result of the pseudo Jahn-Teller effect. (15 refs.)

72361 Random fields in disordered magnetics with Jahn-Teller ions. M.A.Ivanov (Inst. of Metal Phys., Acad. of Sci., Kiev, Ukrainian SSR).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.26-38 (April 1983).
The character of distribution of random fields acting on a two-fold degenerate orbital E-term is investigated. The distribution functions for deformational and Coulomb fields caused by point defects are found. Random fields of exchange type on Jahn-Teller ions in crystals with a spinel structure are also examined. Estimates of distribution width for different fields are performed. The influence of random fields on the structure phase transition temperature and also on the behaviour of specific heat, elastic modul and magnetic anisotropy of crystals is analysed. (21 refs.)

71.70E Spin-orbit coupling, Zeeman, Stark and strain splitting

72362 Unified theory of the electronic Stark effect in molecular crystals. R.W.Munn (Res. School of Chem., Australian Nat. Univ., Canberra, Australia).
Chem. Phys. (Netherlands), vol.76, no.2, p.243-8 (15 April 1983).
A compact expression for the energy of an assembly of polar polarizable molecules in an external electric field is derived with the help of the inverse dielectric function. The expression leads to an economical derivation of the energy shifts and splittings in the electronic Stark effect in molecular crystals. Previous results are unified by verifying their equivalence and correctness. (19 refs.)

72364 Structure and magnetism in a hydroxy bridged binuclear copper(II) system with a 'tunable' binuclear centre. L.K.Thompson (Dept. of Chem., Memorial Univ. of Newfoundland, St. John's, Newfoundland, Canada).
Can. J. Chem. (Canada), vol.61, no.3, p.579-83 (March 1983).
The molecular structure of $[Cu_2(PAP)(OH)(IO_3)_3].4H_2O$ (PAP=1,4-di(2′-pyridyl)aminophthalazine) has been determined by single crystal X-ray diffraction $[Cu_2(PAP)(OH)(IO_3)_3].4H_2O$ belongs to the space group $P2_1/c$ with $a=7.266(1)$, $b=15.269(1)$, $c=25870(1)$ Å, $\beta=96.40(1)°$, $V=2852.2$ Å^3, $Z=4$. The copper coordination geometry lies between a square pyramid and a trigonal bipyramid and the two copper(II) centres are bridged by three groups: N_2 (phthalazine), hydroxide, and bidentate iodate, in a structure which is analogous to that reported for $[Cu_2(PAP)(OH)Cl_3].1.5H_2O$. Replacing the chlorine bridge by iodate has the effect of forcing the two metal centres further apart, thus creating a larger Cu-O-Cu bridge angle. This increase in oxygen bridge angle (101° to 114°) is also reflected in the enhanced antiferromagnetic exchange ($-2J(Cl)=201$ cm^{-1}, $-2J(IO_3)=335$ cm^{-1}). Other groups of varying size (e.g. Br, NO_3, SO_4) can act as bridges between the two copper centres in systems of this sort with the resultant variation in copper-copper separation and oxygen bridge angle. 72.00 ELECTRONIC TRANSPORT IN CONDENSED MATTER

(for surfaces, interfaces, and thin films, see 73.)

72.10 THEORY OF ELECTRONIC TRANSPORT; SCATTERING MECHANISMS

72365 A thermodynamic development of generalized Fourier and Ohm conduction laws for anisotropic materials. Y.Ersoy (Dept. of Engng. Sci., Middle East Tech. Univ., Ankara, Turkey).
Int. J. Eng. Sci. (GB), vol.21, no.7, p.835-40 (1983).
Referring to the residual entropy inequality previously derived, the classical Fourier and Ohm conduction laws are generalized for magnetothermoelectrical rigid continuous solids. From these constitutive equations the Maxwell-Cattaneo equation of heat conduction and the Newtonian-Ohm law of electrical conduction come out in a natural way. To describe rather general thermoelectrical effects and the conducting free energy in a linear theory, it is shown that at most six material tensors are needed. (7 refs.)

72366 Kinetics of electron scavenging in bond-disordered media. N.I.Chekunaev, Yu.A.Berlin, V.N.Fleurov (Inst. of Chem. Phys., Acad. of Sci., Moscow, USSR).
J. Phys. C (GB), vol.16, no.13, p.2569-82 (10 May 1983).
A new kinetic theory of electron scavenging controlled by non-classical electron transport in disordered solids has been developed. This theory is based on the percolation approach to the description of a trap-to-trap tunnelling motion of electrons in solid systems with a bond disorder. Such an approach is applied to determine the concentration of trapped electrons as a function of time for a disordered medium containing randomly placed, immobile scavengers. Two limits of direct physical significance have been considered in detail, i.e. the cases when the concentration of trapped electrons is either much less or equal to that of scavenging molecules. The comparison between present results and those obtained by other authors is discussed. (26 refs.)

72367 Friedel sum rule in the second Born approximation. B.K.Agarwal, N.Singh (Dept. of Phys., Allahabad Univ., Allahabad, India).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.319-20 (9 May 1983).
The condition on the impurity potential is derived using the second Born approximation for the phase shift occurring in the Friedel sum rule. The result distinguishes between the donor-and acceptor-type scattering centers. (8 refs.)

72368 Critical behavior of the low-field Hall conductivity at a percolation threshold. D.J.Bergman (Dept. of Phys., Ohio State Univ., Columbus, OH, USA), Y.Kantor, D.Stroud, I.Webman.
Phys. Rev. Lett. (USA), vol.50, no.19, p.1512-15 (9 May 1983).
The critical behavior of the low-field Hall effect in a three-dimensional metal-nonmetal composite near the percolation threshold has been determined for the first time from calculations on a reliable random-resistor-network model. The Hall coefficient R_e is found to diverge as $|p-p_c|^{-g}$, where $g=0.29 \pm 0.05$. (24 refs.)

72369 On the role of the soliton mechanism in the electron transfer along the quasi-one-dimensional molecular structures. M.Sataric (Faculty of Tech. Sci., Inst. of Appl. Fundamental Sci., Novi Sad, Yugoslavia), R.Zakula.
Phys. Status Solidi b (Germany), vol.116, no.2, p.617-32 (1 April 1983).
An expression for the probability of electron transfer from a donor molecule (D) to an acceptor molecule (A) along a quasi-linear molecular chain (biopolymer), to which D and A are attached is derived. Investigated is the case with an indirect interaction caused by modification of Coulomb interaction due to electron transition from D to A and vice versa via a periodical structure, in addition to the direct, resonant interaction of D and A. The indirect interaction may lead to the electron capture by a soliton wave. The one-way transfer of an electron caused by relaxation phenomena for the dynamical system in contact with a thermostat ($T=0$K) is discussed. (11 refs.)

72370 Frequency dependence of the conductivity in presence of an electric field in one dimension: Weak-disorder limit. B.Derrida (Service de Phys. Theorique, CENS, Gif-sur-Yvette, France), R.Orbach.
Phys. Rev. B (USA), vol.27, no.8, p.4694-701 (15 April 1983).
The frequency dependence of the electrical conductivity is examined for a classical hopping model of a random one-dimensional system in the presence of a superposed static electric field. The effect of the field is taken as a constant bias for the left-right jump rates. A general expression is derived for the mean velocity and frequency-dependent conductivity. Explicit evaluation of these equations is given for correlated and uncorrelated hopping rates: (1) in general for high frequencies and (2) to lowest order in the disorder for all frequencies. In the latter case, an initial decrease in $\sigma(\omega)$ for very small ω is found, $\sigma_R=a_0-a_1\omega^2$, $\sigma_I=a_2\omega^3$. For larger frequencies, the conductivity crosses over to the form $\sigma(\omega)=b_0+b_1(i\omega)^{1/2}$, previously calculated by Alexander and Orbach (1981). The a_i, b_i are constants which depend on the strength of the bias and the randomness. The crossover frequency increases with the bias. In addition, the variance in the autocorrelation function is calculated in the long-time limit, for weak disorder in the symmetric case. It is shown that fluctuations do not significantly affect the determination of this quantity under these conditions. (9 refs.)

72.15 ELECTRONIC CONDUCTION IN METALS AND ALLOYS

72371 Graphitized carbon fibers: a new electrical conductor with high strength to weight properties. J.S.Murday, D.D.Dominguez (Naval Res. Lab., Washington, DC, USA).
Nav. Res. Rev. (USA), vol.35, no.1, p.2-13 (1983).
The authors discuss graphitized carbon fibers and show that the mechanical and electrical properties of the fibers approach those of the a-axis of graphite. A comparison of the graphite properties to those of some common metal alloys is presented. The properties of the graphite a-axis are equivalent or better in all respects except for a deficiency of 10-20 in electrical conductivity. However, there are known ways to chemically modify the graphite by intercalation which improve the conductivity by factors of 10-20. The suitability of this chemical modification to fibers and its long-term stability are considered. Finally, the high cost of graphitized carbon fibers and its reduction by improved manufacturing technology is discussed. (22 refs.)

72.15C Electrical and thermal conduction in amorphous and liquid metals and alloys

72372 Resistance of the amorphous magnetic alloy $Fe_{29}Ni_{49}P_{14}B_6Si_2$ as a function of temperature and stress. R.S.Parashar, A.K.Bhatnagar (School of Phys., Univ. of Hyderabad, Hyderabad, India).

J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.56-60 (April 1983).

The stress and temperature dependence of the electrical resistivity of amorphous alloy ribbon $Fe_{29}Ni_{49}P_{14}B_6Si_2$ in the range 77-440K is reported. Tensile stress was applied along the long ribbon axis. Results obtained on the temperature dependence of $\Delta R/R_{300}$ show that at low temperatures (<320K) the tensile stress has an effect of increasing the slope while at high temperature it seems to be reversed, indicating the initiation of enhanced structural relaxation process. Curie temperature is found to increase with application of the tensile stress. Ferromagnetic resonance (FMR) and scanning electron microscope observations show that the applied tensile stress induces crystallization into the specimen which is reflected through broad FMR peaks. Crystallites seem to be elongated parallel to the direction of the applied stress. (17 refs.)

72373 Electrical transport in low-resistivity amorphous metals. L.V.Meisel, P.J.Cote (Large Caliber Weapon Systems Lab., US Army Armament Res. & Dev. Command, Watervliet, NY, USA).

Phys. Rev. B (USA), vol.27, no.8, p.4617-27 (15 April 1983).

Diffraction-model calculations incorporating appropriate scattering matrix elements and phonon-ineffectiveness effects (saturation effects) yield results which are consistent with the observed temperature dependence of the electrical resistivity in low-resistivity ($\rho<100$ $\mu\Omega$cm) amorphous alloys. In particular, remarkably good quantitative agreement with available detailed resistivity measurements in *a*-MgZn alloys has been obtained by these methods. The results further indicate that saturation effects, which dominate the temperature dependence of the high-resistivity amorphous metals, are important even for resistivities as low as 50 $\mu\Omega$ cm. (40 refs.)

72374 Effect of hydrogen and deuterium on electronic-transport properties of the metallic glass $Pd_{0.76}Cu_{0.06}Si_{0.18}$. S.Basak (Dept. of Phys., Univ. of Chicago, Chicago, IL, USA).

Phys. Rev. B (USA), vol.27, no.8, p.4754-9 (15 April 1983).

The effect of hydrogen and deuterium on the temperature dependence of resistivity ρ and thermoelectric power S for the metallic glass $Pd_{0.76}Cu_{0.06}Si_{0.18}$ is reported. Between 4.2 and 296K it was found that the addition of hydrogen increases ρ and decreases its temperature coefficient $\alpha=(1/\rho)d\rho/dT$. For $4.2<T<90$K the extra resistivity due to hydrogen $\Delta\rho(T)$, decreases with increasing T in a manner best fitted by the form $a-b[\ln(T/T_K)]^2$, where a, b are constants and $T_K=1$K. For the unhydrogenated glass S is small, negative, and linear in T with a negative slope throughout the range $25<T<210$K in which it was measured. Upon hydrogenation dS/dT becomes less negative. The isotope effect in $[\Delta\rho(T)/\Delta\rho(296\text{K})]$ is very small. These data are discussed in the light of two current models of electronic transport in amorphous metals. (28 refs.)

72375 Nature of a double magnetoresistance peak observed in magnetic breakdown in aluminium. V.L.Ginzburg, V.N.Morgun (A.M. Gorki State Univ., Kharkov, Ukrainian SSR).

Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.459-67 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*

Theoretical studies are made of the characteristic features of the magnetoresistance of aluminium under magnetic breakdown conditions in a narrow range of tilt angles (~3°) of a magnetic field H relative to a fourfold symmetry axis. A calculation is made of the contribution of magnetic breakdown electrons to the conductivity in the case of one- and two-dimensional configurations of electron orbits. The dependences obtained are compared with the experimental data. Weakly temperature-dependent oscillations of the transport coefficients are predicted for the case of two-dimensional magnetic breakdown. (14 refs.) *A.T.*

72376 Two-current conduction model and anisotropic magnetoresistance in transition metal-metalloid glasses. S.N.Kaul (Inst. fur Experimental Phys. IV, Ruhr Univ. Bochum, Bochum, Germany).

Phys. Status Solidi b (Germany), vol.116, no.2, p.K99-104 (1 April 1983).

The results of anisotropic magnetoresistance (AMR) measurements are presented for some Fe-B and Co-B metallic glasses with Fe (Co) replaced by Co, Ni (Ni) and also for amorphous $(Fe\text{-}Ni)_{80}B_{20}$ and $(Fe\text{-}Ni)_{80}P_{14}B_6$ alloys. The author discusses these results in the light of various theoretical models. (17 refs.)

72.15L Relaxation times and mean free paths

72377 Importance of electron-phonon processes in the inelastic lifetime of conduction electrons. G.Bergmann (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany).

Solid State Commun. (USA), vol.46, no.4, p.347-9 (April 1983).

The temperature of conduction electrons can be raised above the lattice temperature by a high electric current density. The achieved temperature difference is proportional to the electron-phonon relaxation time. Weak localization yields information about the electron temperature and allows the conclusion that electron-phonon processes are an essential determinant for the inelastic lifetime of the conduction electrons. (16 refs.)

72378 Threshold behavior of charge-density waves pinned by impurities. D.S.Fisher (Bell Labs., Murray Hill, NJ, USA).

Phys. Rev. Lett. (USA), vol.50, no.19, p.1486-9 (9 May 1983).

A time-dependent mean-field theory of the nonlinear electric field response of a charge-density wave pinned by impurities is implemented. It is found that above a threshold electric field E_T, the charge-density wave moves with velocity $v\propto(E\text{-}E_T)^{3/2}$. Some general discussion of the behavior as a function of dimension is included. (16 refs.)

72379 Charge density wave transport in $(TaSe_4)_2I$. Z.Z.Wang, M.C.Saint-Lager, P.Monceau, M.Renard (CNRS, Grenoble, France), P.Gressier, A.Meerschaut, L.Guemas, J.Rouxel.

Solid State Commun. (USA), vol.46, no.4, p.325-8 (April 1983).

The authors report nonlinear transport properties below the metal-insulator transition temperature $T_0=263$K in the halogened metal transition tetrachalcogenide $(TaSe_4)_2I$. These non linear properties are similar to those of $NbSe_3$ and TaS_3 and indicate that $(TaSe_4)_2I$ is a new compound exhibiting charge density wave transport. (14 refs.)

72380 Low-temperature electrical conductivity of a quasi-one-dimensional substance $Hg_{3-\delta}AsF_6$ ('alchemist's gold'). S.I.Mukhin (Inst. of Steel & Alloys, Moscow, USSR).

Sov. Phys.-JETP (USA), vol.56, no.2, p.350-8 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.634-8 (Aug. 1982). [received: May 1983]

A derivation is given of the transport equation for the electron-phonon interaction in a quasi-one-dimensional compound $Hg_{3-\delta}AsF_6$. It is shown that this gives rise to different temperature dependences of the electrical conductivity in two adjoining temperature ranges below the Debye value. At the lowest temperatures the scattering by thermal phonons near singular parts of the Fermi surface is important. At higher temperatures, in the case of a sufficiently large curvature of the planes forming the Fermi surface, the scattering of electrons by short-wavelength phonons predominates. The existence of two mutually perpendicular pairs of Fermi planes in $Hg_{3-\delta}AsF_6$ determines the characteristics of the relaxation of quasimomentum in this system. The theory is in qualitative agreement with experiment. (15 refs.)

72381 Stabilization under pressure of the metallic state in electrically conducting organic tetraselenotetracene salts $(TSeT)_2Br_xCl_{1-x}$. A.V.Zvarykina, V.N.Laukhin, E.E.Yurchakevich, E.B.Yagubskii (Inst. of Chem. Phys., Acad. of Sciences, USSR).

Sov. Phys.-JETP (USA), vol.56, no.2, p.448-51 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.799-805 (Aug. 1982). [received: May 1983]

Under an applied hydrostatic pressure, tetraselenotetracene complexes of composition $(TSeT)_2Br_xCl_{1-x}$ ($0\leq x\leq 1$) undergo a first-order phase transition to a new metallic state which is stable on cooling over the whole temperature range down to 1.3K. The pressure at which this transition takes place decreases linearly with increasing x from 5 kbar for $(TSeT)_2Cl$ to 2.2 kbar for $(TSeT)_2Br$. The resistance of the high-pressure phase of the complexes studied falls practically linearly with decreasing temperature and below 10K becomes the residual resistance characteristic of each composition. 72382 Longitudinal diffusion of nonequilibrium carriers in thin semiconductors. V.N.Ovsyuk (Inst. of Semiconductor Phys., Acad. of Sci., Novosibirsk, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1383-6 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2146-51 (Dec. 1982). [received: May 1983]
A theoretical study is made of the diffusion of nonequilibrium carriers along the surface of a semiconductor in the case when a space charge layer is present near the surface. It is shown that in the case of doped semiconductors with a sufficiently wide gap or at low temperatures there is a certain limiting value of the surface band bending above which the longitudinal diffusion length becomes greater than the real length of a sample. The dependences of the characteristic distances in longitudinal diffusion and lateral photo-EMF on the surface potential and steady-state illumination are obtained. (11 refs.)

72383 Proton and deuteron bombarded $Ga_{0.47}In_{0.53}As$. K.Steeples, G.Dearnaley (AERE Harwell, Didcot, England), I.J.Saunders.
Appl. Phys. Lett. (USA), vol.42, no.8, p.703-5 (15 April 1983).
Large increases in resistivity of $Ga_{0.47}In_{0.53}As$ have been observed due to bombardment with hydrogen ion isotopes. After damage factors due to mass and dose of the implanted isotopes have been taken into account, the high resistivity values of proton and deuteron bombarded $Ga_{0.47}In_{0.53}As$ agree, contrasting with previous observations in GaAs. An explanation is offered. (7 refs.)

72384 Measurements of electrical conductivity of impurity binary solutions. J.Piotrowska-Szczepaniak (Inst. of Phys., Silesian Univ., Katowice, Poland).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.579-82 (April 1983).
Presents results of measurements of electrical conductivity for the binary solution nitrobenzene-hexane with critical x_c and noncritical concentration, pure and also doped by CCl_4. In the two-phase region the temperature dependence of electrical conductivity satisfies the equation: $|\sigma_1\text{-}\sigma_2| = A\epsilon^\beta$ where $\epsilon=(T\text{-}T_c)/T_c$ with $\beta=0.35\pm0.05$. Introduction of an impurity does not change the value of the critical index. (5 refs.)

72385 Electrical conductivity of single crystal nickel tungstate. R.Bharati, R.A.Singh (Dept. of Phys., Univ. of Gorakhpur, Gorakhpur, India), B.M.Wanklyn.
J. Mater. Sci. (GB), vol.18, no.5, p.1540-2 (May 1983).
Measurements of a.c. and d.c. electrical conductivity in crystals of nickel tungstate, in the temperature range 300 to 1100K, are presented. $NiWO_4$ is found to be a semiconductor with a band gap of 2.10 eV. The nature of the electrical conduction is discussed in the light of various conduction models. (16 refs.)

72386 Field-property bounds for porous sintered ceramics. P.Nikolopoulos (Dept. of Chem. Engng., Univ. of Patras, Patras, Greece), G.Ondracek.
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.238-41 (April 1983).
Three sets of equations provide upper and lower values bounding the experimentally obtained electrical and thermal conductivities as well as the magnetic permeabilities (≃'field properties') of porous ceramics. These equations are as I-order upper bound: $\phi_P=\phi_M(1-P)$ (ϕ_P=effective field property of the porous material, ϕ_M=field property of the nonporous material, P=porosity), and as I-order lower bound; $\phi_P=\phi_M(1-P)^7$. Closer bounds corresponding to isotropic porous materials are the II-order upper bound: $\phi_P{}^{I\text{-}I}=\phi_M[2(1-P)/(2+P)]$, and the II-order lower bound: $\phi_{PIII}=\phi_M(1-P)^3$. Even closer bounds, referring to isotropic porous materials containing closed, unconnected pores are the III-order upper bound: $\phi_P{}^{III}=\phi_M(1-P)^{3/2}$, and the III-order lower bound: $\phi_{PIII}=\phi_M(1-P)^3$. (31 refs.)

72387 Electronic conductivity, Seebeck coefficient, and defect structure of $La_{1-x}Sr_xFeO_3$ (x=0.1, 0.25). J.Mizusaki, T.Sasamoto, W.R.Cannon, H.K.Bowen (Dept. of Materials Sci. & Engng., MIT, Cambridge, MA, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.247-52 (April 1983).
The electrical conductivity and Seebeck coefficients of $La_{1-x}Sr_xFeO_3$ (x=0.1, 0.25) were measured as a function of oxygen partial pressure, P_{O2}, at T=900° to 1300°C. The electrical conduction was p type in the higher P_{O2} range, and n type in the lower P_{O2} range. The Seebeck coefficient indicated that the conduction was due to electron hopping between Fe^x_{Fe} and Fd_{Fe} in the higher P_{O2} range and electron hopping between Fe'_{Fe} and Fe^x_{Fe} in the lower range. The carrier concentrations were calculated from the values of electrical conductivity and Seebeck coefficient. From the P_{O2} dependences of the carrier concentrations, the defect structure of $La_1\_Sr_xFeO_3$ was determined. It was found that the electrical properties can be described by considering the imperfections Sr'_{La}, $V_{\ddot{O}}$, Fe_{Fe}, and Fe'_{Fe}. (12 refs.)

72388 Electrical conductivity of 2,4-dinitrosoresorcinol and its complexes. M.S.Masoud, B.S.Farag, Y.A.Swan, T.M.Salem, M.M.El Essawy (Chem. Dept., Univ. of Alexandria, Alexandria, Egypt).
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.209-13 (May 1983).
Electrical conductivity measurements of 2,4-dinitrosoresorcinol (DNR) and its complexes were measured in the temperature range 20-115°C to give faint semiconducting behaviour for these systems. The conductivity values of the bis Co, Ni, Cu and Zn systems indicated that the metal ion forms a bridge between the two ligands facilitating the transfer of current carriers with some degree of delocalization in the excited state. As the iron content in the complexes increased, a gradual increase of electrical conductivity occurred, that might be due to lattice imperfections. (28 refs.)

72389 The resistivity inhomogeneity and the maximum possible mean resistivity of neutron-transmutation doped silicon. T.Gessner (Dept. of Phys., Tech. Univ. of Dresden, Dresden, Germany), B.Schmidt.
J. Phys. D (GB), vol.16, no.5, p.861-8 (14 May 1983).
Neutron-transmutation doping of silicon stimulates to a high degree the production of high resistivity n-type silicon, adjustable in the resistivity range of ρ_n=1...100 kΩ cm. Theoretical analysis of the resistivity inhomogeneities of neutron-transmutation doped silicon (NTD-Si) and the maximum possible mean resistivity as a function of the electrical parameters of the p-type Si starting material is presented. Theoretical and experimental results are compared in the resistivity range ρ_n=2-50 kΩ cm. (12 refs.)

72390 Electrical conduction in cobalt-phosphate glasses. C.A.Hogarth, M.J.Basha (Dept. of Phys., Brunel Univ., Uxbridge, England).
J. Phys. D (GB), vol.16, no.5, p.869-78 (14 May 1983).
Measurements are reported on the DC and AC conductivities of cobalt-phosphate glasses over a temperature range from room temperature to 553K. A polaronic model is shown to be generally applicable to conduction in these materials. The results of the AC measurements are indicative of a hopping process of some kind. (15 refs.)

72391 Ternary copper oxides with the rutile structure: the compounds $Ti_{1-x}Cu_{x/3}Nb_{2x}/_3O_2$. A.Grandin, M.M.Borel, C.Michel, B.Raveau (Lab. de Cristallographie, Chimie et Phys. du Solide, L.A. ISMRA, Univ. de Caen, Caen, France).
Mater. Res. Bull. (USA), vol.18, no.3, p:239-46 (March 1983).
A copper titanoniobate $Ti_{1-x}Cu_{x/3}Nb_{2x/3}O_2$, with rutile structure, has been synthesized for $0\leq x\leq 0.9$, and its crystallographic data have been determined. The study of its electrical and magnetic properties, shows that this solid solution is an n-type semiconductor, whose conductivity increases with the copper content from 10^{-7} $(\Omega\ cm)^{-1}$ for x=0.10 to 10-^{-4} $(\Omega\ cm)^{-1}$ for x=0.80 at room temperature. A succinct investigation of the system $CuTa_2O_6\text{-}TaO_2$, allowed the authors to obtain isostructural oxides with similar conductivities indicating that the 3d titanium orbital is mainly involved in the conduction band of these oxides. The ESR spectra of Cu^{II} ions in these oxides have been obtained at 77K. They suggest nonlinear Cu^{2+} ion pair interactions in the range $0.02\leq x\leq 0.20$. (17 refs.)

72392 Electrical properties of sintered $EuTiO_3\text{-}EuNbO_3$. K.Ishikawa, G.-y.Adachi, J.Shiokawa (Dept. of Appl. Chem., Osaka Univ., Osaka-fu, Japan).
Mater. Res. Bull. (USA), vol.18, no.3, p.257-62 (March 1983).
Two-phase sintered products $[yEuTiO_3+(1\text{-}y)EuNbO_3]$ were investigated as electrical-resistor materials. Electrical resistivities of the products did not depend on y in the range $0<y<0.96$, and rapidly incresed with increasing y over y=0.96, and were semiconductors at $y>0.96$. Thermal coefficients of resistivity for sintered products varied continuously with y, and became a maximum of 2.8×10^{-3} K^{-1} at y=0.75 and a minimum around y=1.00. The coefficient was positive at $y<0.96$ and negative at $y>0.96$. The absolute value of the thermal coefficient of resistivity took a minimum value when $(1/\rho)$ $(d\rho/dT)=0$, at y=0.96. (7 refs.)

72393 Preparation and electrical conductivity of $Cr_2V_2WO_{10}$ and $Cr_2Nb_2WO_{10}$ with the rutile structure. K.R.Nair, M.Greenblatt, W.H.McCarroll (Dept. of Chem., Rutgers Univ., New Brunswick, NJ, USA).
Mater. Res. Bull. (USA), vol.18, no.3, p.309-14 (March 1983).
Polycrystalline samples of $Cr_2V_2WO_{10}$ and $Cr_2Nb_2WO_{10}$, isostructural with the rutile type $FeNbO_4$ have been prepared. The compounds are nonstoichiometric with respect to all the constituent metal ions. Their crystallographic parameters and electrical resistivities have been characterized. The stabilization of rutile structure in these compounds is attributed to electronic effects. (15 refs.)

72394 Crystal structure of $(DPPP)(TCNQ)_5(H_2O)$ and electrical properties of the mixed valence TCNQ salts of diquaternised 1,3-bis(4-pyridyl)propane. G.J.Ashwell (Dept. of Chem., Sheffield City Polytech., Sheffield, England), S.C.Wallwork, P.J.Rizkallah.
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.359-69 (1983).
The conductivities and thermoelectric EMFS of an isostructural series of TCNQ salts are reported together with the crystal structure of $(DPPP)(TCNQ)_5(H_2O)$, representative of the series. The 1:5 salt has a monoclinic subcell, space group $P2_1/c$, with a=12.73(2), b=3.87(2), c=28.47(10) Å, β=107.9(4)°. The TCNQs stack plane-to-plane in columns, parallel to **b**, with (i) an average interplanar spacing of ~3.3 Å and (ii) an exocyclic double bond to quinonoid ring overlap of adjacent molecules. The hydrated cation lattice shows no long-range order. $(DPPP)(TCNQ)_5(H_2O)$ and its isostructural congeners, $(DHPP)(TCNQ)_4(H_2O)$, $(DMPP)(TCNQ)_{4-1/2}(H_2O)$ and $(DEPP)(TCNQ)_5(H_2O)$, are small band gap semiconductors. The room temperature conductivities, determined parallel to **b**, are in the range 0.05 to 100 S cm^{-1}. (24 refs.)

72395 Resolution of the conductivity dilemma in liquid solutions of alkali metals in alkali halides. W.W.Warren,Jr., S.Sotier, G.F.Brennert (Bell Labs., Murray Hill, NJ, USA).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1505-8 (9 May 1983).
Nuclear magnetic resonance measurements are reported for liquid Na-NaBr, Cs-CsCl, and Cs-CsI solutions containing less than 10 mole% metal. Correlation of the resonance shifts, relaxation rates, and DC electrical conductivity shows that the electronic mobility is independent of concentration in Na-NaBr, in sharp contrast with the cesium solutions. The results provide an explanation for the apparently anomalous electronic conductivity observed in liquid-sodium-sodium-halide solutions. (22 refs.)

72396 The non-parabolicity of the n-Si conduction band caused by elastic deformation along the [111] direction. P.I.Baranskii, V.V.Kolomoets, S.S.Korolyuk (Inst. of Semiconductors, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K109-12 (1 April 1983).
The authors study the piezoresistance of n-Si arising at uniaxial elastic deformation along the [111] direction (in absence of current carrier redistribution between individual valleys) due to the deformation-induced change of the effective mass. (4 refs.)

72397 Electrical conductivity of amorphous V_2O_5. C.Sanchez, R.Morineau, J.Livage (Lab. de Spectrochimie du Solide, Univ. Pierre et Marie Curie, Paris, France).
Phys. Status Solidi a (Germany), vol.76, no.2, p.661-6 (16 April 1983).
Electrical conductivity of bulk amorphous V_2O_5 obtained by splat cooling is measured in the temperature range 360 to 150K. A continuous decrease of the activation energy W deduced from a plot of ln (σT) vs. T^{-1} is observed in the whole range. Such a behaviour is typical of small polaron hopping in amorphous transition metal oxides. The temperature dependence of the electrical conductivity is analyzed according to two different models. The first one describes the structural disorder as a random distribution of the potentials while the second one, suggested by Killias, takes into account a random distribution of the hopping distances. Both models agree with the experiments and yield values in good agreement with previous results obtained with amorphous V_2O_5 thin films and V_2O_5 based glasses. (24 refs.)

72398 Quantum correlations to conductivity and energy relaxation in InP and InSb. A.P.Long (Cavendish Lab., Univ. of Cambridge, Cambridge, England), M.Pepper.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.75-7 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The authors present results on conduction in the metallic impurity band of InP at low temperatures. Below 4K, in zero magnetic field, they observe a $T^{1/2}$ correction to the conductivity consistent with the Coulomb interaction model, although the sign of the change is not in agreement with theory. The

observation of a negative magnetoresistance also indicates the role of localization in the conduction process and the authors have attempted to separate the two mechanisms by measuring for both $\omega_c\tau<1$ and $\omega_c\tau>1$. They have measured the energy relaxation time in InSb for various electron and lattice temperatures. The results are discussed in terms of energy loss via acoustic piezoelectric, deformation potential and polar optical scattering. They have measured the electronic specific heat on the insulating side of transition and find it is consistent with a small density of states, but not a gap. (11 refs.)

72399 Investigation and analysis of the temperature dependence of the Hall effect in liquid tellurium. V.M.Glazov, V.B.Kol'tsov (Inst. of Electronic Technol., Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1368-70 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2121-5 (Dec. 1982). [received: May 1983]
A precision method and highly accurate electronic apparatus were used to investigate the temperature dependences of the electrical conductivity, thermoelectric power, and Hall effect of tellurium near the melting point both in the solid and liquid states. The changes in the properties observed on heating the melt were attributed to changes in the volume fraction of the chain component of the structure, calculated from the viscosity data. Calculations of the Hall coefficient carried out on a structure model of liquid tellurium allowing for the spin-orbit interaction gave results close to the experimental data. (15 refs.)

72400 Electrical conductivity of polycrystalline semiconductors. V.G.Kobka, R.P.Komirenko, Yu.V.Kornyushin, Yu.P.Medvedev, O.V.Tretyak (Inst. of Metal Phys., Acad. of Sci., Kiev, Ukrainian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1404-5 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2176-8 (Dec. 1982). [received: May 1983]
The authors consider the nature of electrical conduction of a unipolar semiconductor as a function of the grain size, degree of doping, and other parameters. They show that different types of conduction mechanism (from barrier to disordered) may occur depending on the relationships between the parameters. (8 refs.)

72401 Behavior of silicon in indium antimonide. M.N.Kevorkov, A.N.Popkov, N.S.Rytova, V.S.Uspenskii (State Sci.-Res. & Design Inst. of Rare-Metal Industry, Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1429-30 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2209-11 (Dec. 1982). [received: May 1983]
The authors study the influence of Si on the electrophysical parameters of indium antimonide. Electrical conductivity, carrier mobility and carrier density measurements are described at 77K. (8 refs.)

72402 Correlation of electrical resistivity and heat capacity of silicides of rare-earth metals with the composition R_5Si_4. Yu.V.Serdyuk, R.P.Krentsis, P.V.Gel'd (S.M. Kirov Ural Polytech. Inst., Krasnoyarsk, USSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1779-80 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3141-2 (Oct. 1982). [received: April 1983]
The authors have experimentally investigated the electrical and thermal characteristics of isostructural silicides of rare-earth metals with the composition R_5Si_4 (R=Cd, Tb, Dy, Ho), which are ordered ferromagnetically at low temperatures. The properties of these substances are described well within the framework of RKKY theory. The electrical resistivity of the silicides was measured in the temperature range from 4.2 to 360K by the standard potentiometric method. The heat capacity of silicides R_5Si_4 was studied with a low-temperature adiabatic calorimeter. (6 refs.)

72403 The effect of pressure to 140 kbar on the electrical properties of $CeCu_2Si_2$. F.G.Aliev, N.B.Brandt, V.V.Moshchalkov, V.I.Sidorov, R.V.Lutsiv (M.V. Lomonosov State Univ., Moscow, USSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1786-7 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3151-4 (Oct. 1982). [received: April 1983]
The authors have studied the temperature dependence of the resistivity $\rho(T)$ of single crystal $CeCu_2Si_2$ over the range of temperatures $1.8 \leq T \leq 300K$ at pressures p up to 140 kbar. They conclude that hydrostatic pressure induces a transition from a Kondo lattice state ($p \doteq 0$, $v=3.05$) to a state with a variable cerium valence ($p \lesssim 120$ kbar, $3<v<4$). This transition takes place smoothly; that is, the position of the 4f level and its occupation number are continuous functions of the pressure. Since $\rho(T)$ for $p=120$ and 140 kbar differ very little, it is probable that the cerium ions are already in the state Ce^{4+} for $p \gtrsim 120$ kbar. If the local maximum in $\rho_{300}(p)$ is interpreted in terms of the maximum density of 4f states passing through ϵ_F, then $p \simeq 65$ kbar corresponds to the state with an intermediate cerium valence $v=3.5$. 72.20H High-field and nonlinear effects

72404 Electron transport in InP at high electric fields. T.H.Windhorn, L.W.Cook, M.A.Haase, G.E.Stillman (Electrical Engng. Res. Lab., Univ. of Illinois at Urbana-Champaign, Urbana, IL, USA).
Appl. Phys. Lett. (USA), vol.42, no.8, p.725-7 (15 April 1983).
The high field (>30 kV/cm) electron drift velocity in *n*-type (100) InP has been measured at temperatures from 95 to 400K and electric field strengths up to 215 kV/cm using a fixed frequency (7.54 GHz) microwave time-of-flight technique. The velocity decreases monotonically with increasing electric field strength at all temperatures over the entire range of field strengths investigated. At 300K the electron drift velocity in InP is 1.2 times the velocity in GaAs at 150 kV/cm, and increases to 1.34 times the velocity in GaAs when the field is lowered to 30 kV/cm. (20 refs.)

72405 Two-dimensional hot-electron transport in quantum-well structures of polar semiconductors. D.Chattopadhyay, A.Ghosal (Inst. of Radio Phys. & Electronics, Calcutta, India).
J. Phys. C (GB), vol.16, no.13, p.2583-6 (10 May 1983).
The drift velocity of hot electrons itinerant two dimensionally in a semiconductor quantum-well structure is calculated at different lattice temperatures on a displaced Maxwellian model. Interactions with deformation potential acoustic and polar optic phonons are considered using the analytic expressions obtained on the basis of a momentum conservation approximation. Contrary to a previous prediction, no negative differential resistance is obtained. (7 refs.)

72406 Electrical properties of carbon-polymer composites. E.K.Sichel, J.I.Gittleman (RCA Labs., Princeton, NJ, USA), P.Sheng.
J. Electron. Mater. (USA), vol.11, no.4, p.699-747 (July 1982). [received: Nov. 1982]
Both the experimental and theoretical aspects of the transport of electric charge in carbon black-polymer composites are reviewed. The morphology of these composites is discussed emphasizing its influence on the transport which is dominated by tunneling of electrons between adjacent carbon clusters and through the polymer film which separates them. The tunneling, which is enhanced by thermal fluctuations, leads to a resistivity $\rho(T) \propto \exp[T_1/(T+T_G)]$ at low electric fields and to nonlinear effects at high electric fields which are also a function of $T_1/(T+T_0)$. This tunneling mechanism is compared with the mechanisms dominant in cermets and amorphous semiconductors. (41 refs.)

72407 Resonance energy transfer in activationless hopping conductivity. A.A.Berezin (Dept. of Engng. Phys., McMaster Univ., Hamilton, Ontario, Canada).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1520-3 (9 May 1983).
Activationless hopping conductivity in a strong electric field is caused by downward jumps of localized carriers along the electric field. Here, the specific mechanism of energy release is considered, which involves an energy-transfer process when energy gained by a downward jump of one electron is radiationlessly transferred to another electron, allowing it to make an upward energy jump. An estimate shows that such processes may provide a noticeable contribution to the total hopping conductivity. (13 refs.)

72408 On *I-U* characteristics of semiconductor structures with inhomogeneous mobility profile. A.M.Belyantsev, M.N.Drozdov (Appl. Phys. Inst., Acad. of Sci., Gorkii, USSR).
Phys. Status Solidi a (Germany), vol.76, no.2, p.721-8 (16 April 1983).
The possibility of N- and S-shaped current-voltage characteristics of semiconductor structures with a inhomogeneous mobility profile is shown to appear in crossed electric and magnetic fields. This effect is due to the carrier redistribution. (12 refs.)

72409 Hot electron conduction of PbTe and $Pb_{1-x}Sn_xTe$. A.Krotkus, T.Lideikis, A.Plytnikas, I.Simkiene (Inst. of Semiconductor Phys., Acad. of Sci., Vilnius, Lithuanian SSR).
Solid-State Electron. (GB), vol.26, no.6, p.605-9 (June 1983).
Experimental and theoretical studies have been made of electron transport and hot electron effects in PbTe and $Pb_{1-x}Sn_xTe$ as a function of alloy composition. Pulsed measurements of the current-voltage characteristic, Hall effect, and the potential distribution were made on epitaxial samples. Current instabilities and high field domain formation were observed. Monte-Carlo calculations of the velocity-field characteristic including the scattering into conduction band W-valleys were performed. Reasonable agreement was obtained for the threshold field dependence on alloy composition. (19 refs.)

72410 'Oblique' field domains as illustrated by the Sasaki effect in semiconductors. Z.S.Gribnikov (Inst. of Semiconductors, Acad. of Sci., Ukrainian SSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.401-5 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.718-26 (Aug. 1982). [received: May 1983]
In an isotropic semiconductor with negative differential resistance, the walls of the produced strong- and weak-field domains are inclined at an oblique angle to the current direction (and not at a right angle as in the isotropic case). The theory of such oblique field domains, with the Sasaki effect in a two-valley semiconductor as the example, is developed for samples with limited transverse dimensions. The distinguishing feature of this example is that the negative resistance and the anisotropy itself are induced by heating of the carriers in the longitudinal and transverse fields and are interrelated. The inclination angles of the oblique domain walls depend on the flowing current and in one of the limiting cases they can be almost parallel to the current direction. A correct value of a strong-field domain velocity can be obtained only if the inclination is taken into account. (10 refs.)

72.20J Charge carriers: generation, recombination, lifetime, and trapping

72411 Diffusion length of holes in *n*-InP. V.Diadiuk, S.H.Groves, C.A.Arimento, C.E.Hurwitz (Lincoln Lab., MIT, Lexington, MA, USA).
Appl. Phys. Lett. (USA), vol.42, no.10, p.892-4 (15 May 1983).
By measuring the photocurrent as a function of reverse bias for InP photodiodes with a range of junction depths, the hole diffusion length L_p of epitaxial *n*-type InP ($n\sim1.5\$09M10^{16}$ cm^{-3}) was determined to be approximately 12 μm. This value of $L_p$is an order of magnitude larger than that determined by the electron beam induced current and surface photovoltage techniques. Reasons for these discrepancies, which involve geometrical and material considerations, respectively, are discussed. (14 refs.)

72412 On EBIC versus time measurements in thin semiconductor layers with the scanning electron microscope. A.Jakubowicz (Inst. of Electron Technol., Tech. Univ. of Wroclaw, Wroclaw, Poland).
Phys. Status Solidi a (Germany), vol.76, no.2, p.729-34 (16 April 1983).
Recent results are given of EBIC vs. time measurements in thin semiconductor layers with the scanning electron microscope (SEM). This paper continues the discussion which started in a previous paper (see A. Jackubowicz, Solid-State Electron., vol.23, p.635, 1980). (7 refs.)

72413 Current transport across a grain boundary in polycrystalline semiconductors. Chih-Yuan Lu (Inst. of Electronics, Nat. Chiao Tung Univ., Hsin-Chu, Taiwan), N.Chau-Chun Lu.
Solid-State Electron. (GB), vol.26, no.6, p.549-57 (June 1983).
A unified approach to current transport across a grain boundary in polycrystalline semiconductors is developed. The resulting expressions for potential barrier and *J-V* characteristics are of general validity. The study concentrates on the carrier-trapping effect, and the trapping-state density can be monoenergetic, continuous, gaussian, or any reasonable distribution. By solving Poisson's equation under suitable boundary conditions without the depletion approximation, a single formulation is obtained for potential barriers in two adjacent grains with different sizes and doping levels. The grain-boundary scattering effect is approximated as a rectangular potential barrier. The voltage division of an applied bias across the junction is determined under the current-continuity conditions. A single expression with suitable computational simplicity is then presented for the *J-V* characteristics across the many-valley semiconductor/grain-boundary/semiconductor junction. (37 refs.)

72414 Carrier recombination and lifetime in highly doped silicon. J.G.Fossum, R.P.Mertens, D.S.Lee, J.F.Nijs (Dept. of Electrical Engng., Univ. of Florida, Gainesville, FL, USA).
Solid-State Electron. (GB), vol.26, no.6, p.569-76 (June 1983).
The predominance of phonon-assisted band-band Auger recombination in highly doped silicon is demonstrated by showing that no recombination mechanism involving common (unavoidable) defects in silicon can yield carrier lifetimes that are consistent with the measured lifetimes, which exhibit an inverse-quadratic doping-density dependence, and/or with their temperature dependence. Both trap-assisted-Auger and Shockley-Read-Hall recombination mechanisms are considered, and dependences of the defect density on the doping density, which are implied by theory and experiment, are accounted for. (38 refs.)

72415 Minority carrier recombination in heavily-doped silicon. M.S.Tyagi (Dept. of Electrical Engng., Indian Inst. of Technol., Kanpur, India), R.Van Overstraeten.
Solid-State Electron. (GB), vol.26, no.6, p.577-97 (June 1983).
A review of present understanding about the minority carrier recombination in silicon with dopant concentration in the range of 10^{18}-10^{20} cm^{-3} is presented. After providing a short phenomenological description of carrier recombination processes and lifetime, the main theories of carrier recombination in a semiconductor are briefly reviewed and their expected contributions to carrier recombination in silicon at heavy doping are indicated. The various methods used for measuring the minority carrier lifetime in heavily doped silicon are described and critically examined. Four different mechanisms are examined to explain the available lifetime data. (86 refs.)

72416 Carrier recombination at grain boundaries and the effective recombination velocity. W.Hwang, E.Poon, H.C.Card (Dept. of Electrical Engng., Columbia Univ., New York, NY, USA).
Solid-State Electron. (GB), vol.26, no.6, p.599-603 (June 1983).
The recombination of exces minority carriers at grain boundaries, or other interfaces with space-charge regions, is treated theoretically for general energy distributions of interface states (recombination centers). The distinction is made between minority carrier recombination velocity at the (grain-boundary) interface itself, and the effective recombination velocity for the collection of these carriers by the adjacent space-charge region. Calculations of the effective recombination velocity are made, as a function of the excess minority-carrier concentration at the edge of the space-charge region, since this is the quantity of most convenience for device modelling. (18 refs.)

72417 Negative temperature coefficient of the equilibrium carrier density in self-compensated β-SiC. L.S.Aivazova, V.L.Vinetskii, G.A.Kholodar' (Inst. of Phys., Acad. of Sci., Kiev, Ukrainian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1355-7 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2100-4 (Dec. 1982). [received: May 1983]
Oxygen-doped β-SiC single crystals with relatively few defects exhibited a strong exponential fall of the equilibrium conduction electron density $n(T)$ on increase in temperature to 500K or higher. In a wide range of temperatures the dependence $n(T)$ was described satisfactorily by the concept of an equilibrium self-compensation of *n*-type conduction due to transformation of electrically inactive defects into new defects with an acceptor level. This transformation was stimulated by conduction electrons captured by the acceptor level of the new defects during their formation. (7 refs.)

72418 Cascade capture of carriers in semiconductors under dynamic conditions. V.Karpus, V.I.Perel' (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1373-6 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2129-35 (Dec. 1982). [received: May 1983]
A theory of the cascade capture of carriers is extended to the case of transient carrier generation and to the conditions of photothermal ionization. At low concentrations of the capture centers (traps), the lifetime is governed by the 'search' for centers. At high concentrations the dependences of the dynamic and static lifetimes (governed by the 'descent' time) on the initial carrier energy is important. It is shown that the dynamic lifetime is minimal for the generation of carriers into the percolation level and that it is equal to the time taken to lose an energy kT. (12 refs.)

72419 Drag of electrons by a longitudinal electric wave and sign of the drag force. L.E.Gurevich, V.S.Travnikov (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1407-8 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2180-2 (Dec. 1982). [received: May 1983]
The authors consider the drag of electrons by a longitudinal electric wave (bulk plasmon) in a semiconductor; such a wave may be excited by fast electrons, X-rays, or light. The mechanism of the drag effect is very different from that of the drag by a transverse wave first considered by Barlow (1954). (11 refs.)

72420 Interband recombination of nonequilibrium carriers in p-type $Cd_xHg_{1-x}Te$ ($x\approx0.25$). N.L.Bazhenov, V.I.Ivanov-Omskii, N.N.Konstantinova, V.K.Ogorodnikov (AF Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1424-5 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2202-4 (Dec. 1982). [received: May 1983]
The authors report that in the case of p-type $Cd_x.Hg_{1-x}Te$ crystals with $x\approx0.25$ and a low concentration of recombination centers the temperature dependence of the carrier lifetime τ can be explained by the interband recombination mechanisms in a wide range of temperatures without invoking more complex models. The hole density and mobility in the investigated samples with $x\approx0.25$ were (1-4).10^{15} cm^{-3} and 300-350 cm^2.V^{-1}.sec^{-1}, respectively. A typical temperature dependence of the Hall coefficient R of one of the investigated samples is given. (9 refs.)

72421 Increase in the minority-carrier lifetime in GaAs as a result of irradiation and heat treatment. K.D.Glinchuk, N.S.Zayats, A.V.Prokhorovich (Inst. of Semiconductors, Acad. of Sci., Kiev, Ukrainian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1433-4 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2214 (Dec. 1982). [received: May 1983]
The effects of γ-ray irradiation and heat treatment on the minority-carrier lifetime in GaAs are described. Experiments were carried out on γ-irradiated tellurium-doped low-resistivity n-type GaAs crystals. The changes in the minority-carrier (hole) lifetime τ_h as a result of irradiation and heat treatment were deduced by measuring the photomagnetic EMF after irradiation and after subsequent annealing. (6 refs.)

72422 Hole density and degree of compensation of synthetic *p*-type diamond. O.G.Revin, V.N.Slesarev (Inst. of High-Pressure Phys. Acad. of Sci., Troitsk, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1436-8 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2219-21 (Dec. 1982). [received: May 1983]
Measurements were made of the electrical conductivity of synthetic *p*-type diamond single crystals in a narrow temperature range (283-293K) in order to determine the carrier scattering mechanism. The results and the data on the magnetoresistance and broadening of an acceptor level as a function of the concentration of electrically active impurities were used to determine the electrical resistivity, ionization energy of acceptors, degree of their compensation, hole density, and concentrations of acceptors and donors. Calculation formulas were derived for the electrical resistivity of octahedral samples. (11 refs.)

72423 Influence of the anisotropy of the probabilities of optical transitions of holes on the drag current in semiconductors of *p*-Ge type. E.Normantas, D.Gentsov, M.Moker (Inst. of Semiconductor Phys., Acad. of Sci., Vilnius, Lithuanian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1438-40 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2222-5 (Dec. 1982). [received: May 1983]
The authors calculate the drag current in Ge type semiconductors allowing for the anisotropy of the probabilities of optical transitions of holes due to their interaction with a transverse light wave. They ignore the optical heating of holes and calculate the current in the approximation of the relaxation times of the light holes τ_1 and the heavy holes τ_2, dependent only on the hole energies E_1 and E_2. The anisotropy of the probabilies of hole transitions in the case when holes are scattered by the lattice vibrations and impurities does not justify introduction of such relaxation times. However, since the relevant collision integrals require averaging over the wave vectors of holes, one can expect the anisotropy of the scattering of holes by phonons and impurities to have less effect on the photon drag current than the anisotropy of the probabilities of their optical transitions. (4 refs.)

72424 Thermally stimulated relaxation currents due to forces of nonelectrostatic origin. Yu.A.Gorokhovatskii, A.N.Gubkin, V.K.Malinovskii, B.I.Sturman (Moscow Electronic Engng. Inst., Moscow, USSR).
Sov. Phys. J. (USA), vol.25, no.7, p.607-9 (July 1982). Translation of: *Izv. VUZ Fiz. (USSR)*, vol.25, no.7, p.32-5 (July 1982). [received: May 1983]
It is shown that unusual thermally stimulated relaxation currents can arise in the external circuit on homogeneous heating of an insulator with a polar direction that is in a thermodynamically nonequilibrium state. These currents differ from thermally stimulated depolarization currents in being observed in a specimen that is unpolarized or has been depolarized. The temperature dependence of these relaxation currents is obtained for a particular model. (7 refs.)

72425 Spin-dependent recombination on dislocation dangling bonds in silicon. V.V.Kveder, Yu.A.Osip'yan, A.I.Shalynin (Inst. of Solid State Phys., Acad. of Sci., USR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.389-98 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.699-714 (Aug. 1982). [received: May 1983]
Spin-dependent recombination of free carriers via dislocation dangling bonds is investigated as a function of the temperature and of the light power in magnetic fields 0.04, 3.3, and 12.5 kOe. A model of the effect is proposed on the basis of an analysis of the obtained data. The model makes use of the concept of recombination via the dangling bonds, with preliminary capture of the carriers by intermediate shallow levels assumed to be due to the deformation potential of the dislocation. (25 refs.)

72426 Quantum oscillation of carrier concentation due to Fermi level pinning by doped indium impurities in $Pb_{1-x}Sn_xTe$. S.Takaoka, T.Itoga, K.Murase (Dept. of Phys., Osaka Univ., Toyonaka, Japan).
Solid State Commun. (USA), vol.46, no.4, p.287-90 (April 1983).
The Shubnikov-de Haas like oscillation and rapid increase of the carrier concentration above the quantum limit magnetic field (H_0) are observed in $Pb_{1-x}Sn_xTe$ doped with indium (x=0.33 and 0.35). Experimental results can be reproduced satisfactorily by the calculation based on the Fermi level pinning model due to In-impurities, where the authors take into account the level broadening (Γ) effect of the band structure. It is confirmed that the increasing rate of carrier concentration with respect to magnetic field above H_0 decreases with larger Γ. (18 refs.)

72427 Dependence of the Hall effect on the magnetic field in a model of an inhomogeneous narrow-gap semiconductor. R.V.Pomortsev, A.N.Mezentsev (Inst. of Metal Phys., Acad. of Sci., Sverdlovsk, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1420-1 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2196-9 (Dec. 1982). [received: May 1983]
The authors consider a simple model of an inhomogeneous semiconductor containing regions with n- and p-type conduction. The dimensions of the regions are such that the behavior of carriers can be described by quasiclassical expressions for the electrical conductivity tensors. Inside each region the electrical conductivity tensor is constant and, moreover, it assumes only one of the two values: σ^n for all the n-type regions and σ^p for all the p-type regions. The regions themselves are distributed at random relative to one another. (9 refs.)

72.20N Thermomagnetic effects

72428 Nernst-Ettingshausen coefficient in quantizing magnetic fields in the case of scattering by impurities with an arbitrary radius of action. L.N.Vikhor, L.S.Drapak, S.L.Korolyuk (State Univ., Chernovtsy, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1443-4 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2229-31 (Dec. 1982). [received: May 1983]
The authors calculate the Nernst-Ettingshausen NE coefficient in quantizing magnetic fields for the scattering of carriers on impurities with an arbitrary radius of action. They consider the case in a degenerate semiconductor electron gas. (9 refs.)

72.20P Thermoelectric effects

72429 Influence of thermal annealing on thermoelectric properties of normal and neutron-doped silicon crystals. P.I.Baranskii, E.I.Vidalko, V.V.Savyak, V.P.Shapovalov (Inst. of Semiconductors, Acad. of Sci., Kiev, Ukrainian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1434-6 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2216-19 (Dec. 1982). [received: May 1983]
The authors have investigated the influence of high-temperature annealing and various cooling regimes on some thermoelectric properties of neutron-doped and normal (grown from the melt) silicon crystals. The drag piezothermoelectric power was measured at T=85K for neutron-doped and normal samples in the $X \parallel \nabla T \parallel [001]$ geometry. (6 refs.)

72.30 HIGH-FREQUENCY EFFECTS; PLASMA EFFECTS

72430 Spin polarization of electron-hole plasma in Mn-doped ZnTe. S.I.Gubarev, A.V.Komarov (Phys. Inst., Acad. of Sci., Ukrainian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.28-30 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.446-8 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Nonequilibrium degenerate electron-hole plasma (EHP) in cubic ZnTe:Mn crystals has been investigated. The properties of spin polarization in such crystals are associated with the existence of a strong exchange interaction of free carriers ($S^e=1/2$, $S^h=3/2$) with 3d electrons in Mn^{2+} ions. (6 refs.)

72431 Distribution of relativistic electrons of a high current beam in a solid state target. V.I.Boiko, E.A.Gorbachev, V.V.Estigneev.
Fiz. Plazmy (USSR), vol.9, no.2, p.366-70 (March-April 1983). In Russian. English translation in: *Sov. J. Plasma Phys. (USA)*
An investigation is reported into the penetration and interaction of a high-current electron beam with substances which form a solid-state plasma under the action of the beam. In the general case the problem can be defined as a self-consistent and nonstationary one, requiring the solution of a system of equations consisting of the kinetic equation for relativistic electrons, Maxwell's equation for the electromagnetic field and equations describing the change in the parameters of the medium under the action of the high-current electron beam. Diffusion of the magnetic field in the absorber is not taken into account here. Results obtained indicate that the electric and magnetic fields created by the high current beam alter the distribution of relativistic electrons in a solid state target considerably. (13 refs.) *A.G.C.*

72432 Density profile of the 3D one-component plasma near a hard insulating wall from density functional theory. A.Alastuey, J.J.Weis (Lab. de Phys. Theorique et Hautes Energies, Univ. de Paris Sud, Orsay, France).
J. Phys. C (GB), vol.16, no.13, p.2449-53 (10 May 1983).
A density functional theory recently proposed by Alastuey and Levesque (1982) is applied to the density profile of the three-dimensional one-component plasma near a hard insulating wall. The results are compared with Monte Carlo and HNC calculations in the range of coupling constants $10 \lesssim \Gamma_B \lesssim 30$. (18 refs.)

72433 Distribution of mesoplasma radiation in the direct bias voltage. Ya.K.Balodis, T.Ya.Puritis, A.Yu.Geske.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.54-61 (1983). In Russian.
Integral radiation intensity from separate areas of mesoplasma in the direct bias voltage is studied. Dimensions of the mesoplasma's area with diminished intensity of visible radiation narrow perpendicular to the n^+-p-junction and move into the direction of higher doping silicon while increasing mesoplasma's current density. As a result of the analysis it is suggested that ionization in mesoplasma usually takes place outside, the space charge of the *p-n*-junction and the area of ionization is closely connected with the mesoplasma light emitting areas. (4 refs.)

72434 Thermodynamic properties of equilibrium and non-equilibrium plasmas in GaP. H.Schweizer, A.Forchel, W.Schmid (Phys. Inst., Univ. Stuttgart, Stuttgart, Germany).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.318-20 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Reports the first measurement of the phase diagram of electron-hole liquid (EHL) condensation for a polar compound semiconductor with indirect band structure. Above the critical point the authors observe an electron-hole plasma (EHP) with a density which increases with temperature. In contrast to previous results they find no evidence for a first-order Mott-transition of free excitons into this EHP. (12 refs.)

72435 The e-h plasma in direct-gap GaAlAs under 3-D confinement. M.Capizzi, A.Frova, F.Martelli, S.Modesti, L.G.Quagliano (Istituto di Fisica, Univ. di Roma, Rome, Italy), J.-L.Staehli, M.Guzzi, R.A.Logan, G.Chiaretti.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.333-5 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Uniformly excited e-h plasma in direct-gap $Ga_{1-x}Al_xAs$ under 3-D confinement has been measured by photoluminescence at 2K. A satisfactory fit to experiment in the whole range of densities investigated is given by a theoretical model with k-conservation and collision broadening, using a single value of density and temperature throughout the excited region. The fitted renormalized gap matches closely current theoretical values, independent of composition x. (17 refs.)

72436 Electron-hole plasma in direct gap semiconductors—a new non-equilibrium model. A.Forchel, H.Schweizer, H.Nather, K.M.Romanek, J.Fischer (Phys. Inst., Univ. Stuttgart, Stuttgart, Germany), G.Mahler.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.336-8 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The formation of non-equilibrium electron-hole plasmas in direct gap semiconductors is studied using a phenomenological model for the plasma thermodiffusion. The theoretical results for the plasma density as a function of temperature and band structure are in good agreement with new experimental results from InP and with literature data from different III-V and II-VI compound semiconductors. Including the plasma diffusion in the calculation of lineshapes removes previously reported discrepancies between the experimental and theoretical binding energies. (10 refs.)

72.40 PHOTOCONDUCTION AND PHOTOVOLTAIC EFFECTS; PHOTODIELECTRIC EFFECTS

72437 Photoconductivity enhancement by light trapping in rough amorphous silicon. T.Tiedje, B.Abeles, J.M.Cebulka, J.Pelz (Corporate Res. Labs., Exxon Res. & Engng. Co., Linden, NJ, USA).
Appl. Phys. Lett. (USA), vol.42, no.8, p.712-14 (15 April 1983).
The photoconductivity of amorphous silicon films is shown to be enhanced by a factor of 25 at long wavelengths when the material is deposited on a rough, reflecting substrate. In a solar cell, this light trapping effect would produce a 4.5-mA/cm^2 increase in the short circuit current. (8 refs.)

72438 Photovoltaically active p layers of amorphous silicon. B.W.Faughnan, J.J.Hanak (RCA Labs., Princeton, NJ, USA).
Appl. Phys. Lett. (USA), vol.42, no.8, p.722-4 (15 April 1983).
Studies on amorphous silicon p-n diodes have shown that the p layers are photovoltaically active. J_{sc} of up to 3.4 mA/cm^2 and V_{oc} of 780 mV have been observed. Detailed quantum efficiency measurements were performed as a function of bias voltage, p-layer thickness, and boron doping. The data fit a simple depletion width model in which all photogenerated carriers created inside the depletion region are collected. An additional 'reverse' barrier depletion width is assumed at the interface between the front transparent oxide electrode and the p layer to explain the results. A 10-mm-thick p layer typically used in p-i-n cells could collect up to 1 mA/cm^2 if the electric field in the p layer is greater than 10^5 V/cm. (4 refs.)

72439 Photoconductive response of compensating impurities in photothermal ionization spectroscopy of high-purity silicon and germanium. L.S.Darken (Solid State Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA), S.A.Hyder.
Appl. Phys. Lett. (USA), vol.42, no.8, p.731-3 (15 April 1983).
In photothermal ionization spectroscopy both positive and negative photoconductivity responses have been reported from compensating centers neutralized by minority carriers generated by band-edge light. Here, the response of compensating impurities in both n-type and p-type high-purity ($|N_A$-$N_D| \approx 10^{10}$-10^{12} cm^{-3}) nuclear-detector-grade silicon and germanium is reported. Negative photoconductive responses from compensating impurities were observed only when the distance the photothermally generated majority carriers traveled before recapture by shallow levels was longer than the sample length (contact to contact). The authors propose that in high-purity semiconductors, such as used in this study, it is the contact configuration that is responsible for the apparent rapid recombination of minority carriers which causes negative minority-carrier photoconductivity. n^+nn^+ or p^+pp^+ structures allow multiple traversals through the sample by only majority carriers. The dependence of the band-edge light generated excess carrier density on applied electric field supports this mechanism. (12 refs.)

72440 Polarization-sensitive photovoltaic effect in germanium sulphide single crystals. L.K.Mladzhov (Central Lab. of Sun Energy & New Energy Sources, Bulgarian Acad. of Sci., Sofia, Bulgaria).
Bulg. J. Phys. (Bulgaria), vol.10, no.1, p.57-62 (1983).
The appearance of a photoelectromotive force in rhombic low-symmetry germanium sulphide single crystals has been studied for the first time. The photovoltaic effect was found to be highly sensitive to linear polarized excitation. The photoelectromotive force (FEMF) is shown to be a periodic function of the angle contended between the electric vector E of the exciting polarized light and the crystallographic axes a and b of the crystal. The spectral dependence of FEMF has been studied in the 1.2-2.6 eV excitation energy range at E normal and parallel to the axis a. The photovoltaic pleochroism spectral distribution is characterized by a sharp maximum at 1.72 eV; it changes sign in the region about 1.64 eV. The results obtained are of interest in designing high-sensitive photoreceivers for direct detection of linear polarized radiation. (8 refs.)

72441 Photoelectric properties of pelicular sandwich structures based on cadmium sulphoselenide. E.B.Kaganovich, Yu.N.Maksimenko, S.V.Svechnikov.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.19-23 (1982). In Russian.
The photoelectric parameters and characteristics of two types of sandwich structures (those based on CdSe deposited by thermal vaporisation and by condensation in a quasiclosed space in a vacuum and those based on CdS films deposited by sedimentation during centrifugal separation from a powdery material with a binder) are investigated. The dependences of the magnitude of the impedance and its multiplicity factor on the magnitude and frequency of the voltage applied and the illumination intensities are explained within the framework of their equivalent circuits. (5 refs.) *L.M.H.*

72442 Impulse response of photoconductors in transmission lines. D.H.Auston (Bell Labs., Murray Hill, NJ, USA).
IEEE J. Quantum Electron. (USA), vol.QE-19, no.4, p.639-48 (April 1983).
The response of high-speed photoconductors to picosecond optical pulses is analyzed by representing them as time-varying circuit elements in transmission lines. Expressions are derived for transmitted and reflected waves for photoconductors used both as pulse generators and sampling gates. These results are then used to determine the correlated response of pairs of photoconductors in different transmission line networks. The results provide a basis for estimating the limiting speed of response of this approach to very high-speed electronic measurements. (26 refs.)

72443 Methodology for calculating turn-off transient of photoconductive circuit elements in picosecond optoelectronics. B.Hwang, F.A.Lindholm (Dept. of Electrical Engng., Univ. of Florida, Gainesville, FL, USA), R.B.Hammond.
IEEE J. Quantum Electron. (USA), vol.QE-19, no.4, p.648-57 (April 1983).
A methodology for calculating the transient following sudden removal of photon or mass-particle excitation is developed for semiconductor devices in which high hole-electron recombination rates, rather than short transit times, yield picosecond response time. The name photoconductive circuit element (PCE) is suggested for these optoelectronic transducers. The device consists of a nearly intrinsic active region that contains extremely high concentrations of deep-level states acting as recombination centers. Regions of semiconductors highly doped with shallow donor or acceptor atoms connected to metallic contacts border this active region. In calculating the turnoff transient, criteria are set forth that define nearly ideal ohmic-contact systems and the quasi-neutrality regime of the intrinsic region. If these criteria are met, the turn-off transient becomes a problem in photoconductive decay. For incremental variations in the electron and hole quasi-Fermi voltages much less than the thermal voltage, two characteristic times, assigned to each recombination-center energy level describe electron-hole recombination. InP:Fe photoconductive circuit elements containing eight different Fe concentrations, excited by 780 and 600 nm laser-light pulses and 6 MeV electron pulses, showed a $(1/e)$-fall-time versus Fe-concentration in general accord with results calculated by the methodology. (21 refs.)

72444 Stability of semiconducting TiO$_2$ photoanodes. Fu-Tai Liou, C.Y.Yang (Dept. of Energy & Environment, Brookhaven Nat. Lab., Upton, NY, USA), S.N.Levine.
J. Electrochem. Soc. (USA), vol.130, no.4, p.893-5 (April 1983).
Reported are some striking aging effects observed with relatively high doped TiO$_2$ anodes which have been exposed in the dark to alkaline solutions for somewhat over 100 hr. No detailed explanation for the effects noted is available at this time. (10 refs.)

72445 Photovoltaic properties of thin polymer films. K.Yamashita, T.Suzuki, T.Hino (Dept. of Electrical & Electronic Engng., Tokyo Inst. of Technol., Tokyo, Japan).
J. Vac. Soc. Jpn. (Japan), vol.26, no.1, p.30-4 (1983). In Japanese.
Photovoltaic properties of thin films of PVK-TNF charge transfer complex have been investigated. Thin films of thickness between 10 and 500 nm were formed by the solution casting method. The film thickness can be reproductively controlled by the concentration of polymer solution. Photovoltaic properties were measured in a Au-(thin-film)-Al cell as a function of film thickness. Peaks of the photovoltaic action spectrum coincide with those of light absorption spectrum respectively. The photovoltaic conversion efficiency increases with reducing film thickness, until the efficiency becomes maximum value (about 0.01%) at the thickness of about 100 nm. (7 refs.)

72446 Photoconductive properties of TiO$_2$ powders. F.Kaneko, H.Itoh, M.Takeuchi, H.Nagasaka.
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.61-7 (1982).
Hydrous titanium oxides were precipitated by adding NH$_4$OH to TiCl$_4$ and Ti(SO$_4$)$_2$ solutions, and by hydrolysis in water of Ti(OCH(CH$_3$)$_2$)$_4$. Some of hydrous titanium oxides were dissolved by oxalic acid and reprecipitated by adding NH$_4$OH. Titanium oxide powders were prepared from these hydrous titanium oxide by firing at 500 to 1000°C. Crystal structures of the sample powders were investigated by means of X-ray diffractometry. The photoconductive properties of TiO$_2$ powders depended on the starting materials, reaction temperature for hydrous titanium oxide and firing temperature of hydrous titanium oxide. The photosensitivity of TiO$_2$ powder prepared from hydrous titanium oxide precipitated at 10 to 12°C was larger than that of samples prepared from oxide precipitated at 75 to 80°C. The photosensitivity of all TiO$_2$ powders prepared from Ti(SO$_4$)$_2$ was small. On the other hand, the optimum firing temperature of hydrous titanium oxides was 700°C for all samples. The spectral response curve extended from 310 to 460 nm and showed two peaks in this region for the TiO$_2$ powder with high photosensitivity. (5 refs.)

72447 Photoconductivity and hole transport in polymers of aromatic amine-containing methacrylates. M.Stolka, D.M.Pai, D.S.Renfer, J.F.Yanus (Joseph C. Wilson Center for Technol., Xerox Corp., Rochester, NY, USA).
J. Polym. Sci. Polym. Chem. Ed. (USA), vol.21, no.4, p.969-83 (April 1983).
Substantial hole transport can be achieved in organic polymers simply by incorporating aromatic amine groups into the monomer. Hole mobilities similar to or greater than those in poly(N-vinyl-carbazole) (PVK) were measured in a series of high molecular weight arylamine-substituted polymethacrylates. The hole transport in these polymers is electric-field-dependent as in PVK, varying between E and E^2 within a range of 4×10^4-$\sim9\times10^5$ V/cm. The polymers also exhibit carrier generation in ultraviolet (UV) light in the range of absorption. Synthesis of the monomers, their polymerization, and the general properties of these polymers are discussed. (30 refs.)

72448 The determination of absorption coefficients from the photoresponse of silicon Schottky barriers. S.Mil'shtein, Y.Brada (Dept. of Phys., Ben-Gurion Univ., Beer-Sheva, Israel).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.194-6 (25 April 1983).
A novel approach to the measurement of the absorption coefficient was made through the use of differential photocurrents of Schottky barriers in order to eliminate the influence of unknown surface conditions. By varying the reverse bias on Schottky barriers created by semitransparent Au on Si wafers, the depth of the barrier layer was varied and the resulting photocurrents were used to evaluate the absorption coefficient of the substrate at room temperature. The results are in good agreement with values published in the recent literature. (9 refs.)

72449 Influence of the mobility threshold on the photoconductivity. L.P.Ginzburg (Electrical Engng. Inst. of Communications, Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1400-2 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2171-3 (Dec. 1982). [received: May 1983]
The author shows that there is experimental evidence confirming that for degrees of compensation $\ll 1$ then a mobility threshold exists in the impurity-band photoconductivity at liquid helium temperatures. (14 refs.)

72450 Model of long-term relaxation photoconductivity of GaN:Zn structures. Ya.D.Lebedev, M.D.Shagalov (Polytech. Inst., Vologda, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1428-9 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2207-8 (Dec. 1982). [received: May 1983]
The authors report a study of long-term processes, particularly of the kinetics of growth and decay of the photoconductivity. The experimental results were obtained in the case of excitation with impurity-absorbed light when a sample exhibited a considerable photosensitivity. The general nature of the growth and decay curves of the photoconductivity was the same also in the region of the fundamental absorption band. (4 refs.)

72451 Kinetic theory of the displacement photovoltaic effect in piezoelectrics. V.I.Belinicher, E.L.Ivchenko, B.I.Sturman (Inst. of Automation & Electrometry, Acad. of Sci., Novosibirsk, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.359-66 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.649-61 (Aug. 1982). [received: May 1983]
It is shown that, besides the mechanisms of the photovoltaic effect (PVE) that are connected with the appearance of asymmetry in the electron velocity distribution [V.I. Belinicher and B.I. Sturman, Sov. Phys. Usp. 23, 199 (1980); E.L. Ivchenko and G.E. Pikus, in: Problemy sovremennoi fiziki (Problems of Modern Physics), Nauka, Leningrad, 1980, p.275], there exist independent mechanisms stemming from the displacement of the electrons in R space when they undergo quantum transitions. This displacement PVE is determined by the contributions to the current of the off-diagonal—in the band numbers—density matrix elements. A consistent kinetic theory of the displacement PVE is constructed for band-band and impurity-band transitions. It is shown that the magnitudes of the displacements can be expressed in terms of the phases of the transition matrix elements. The displacement photocurrent is equal to the sum of the ionization, recombination, and scattering currents, which do not depend on the electron and hole mean free paths. The magnitude of the off-diagonal contribution to the current can be comparable to the magnitude of the diagonal contribution. (21 refs.)

72452 Microanalysis of candidate thin and thick film photovoltaic materials. P.E.Russell, C.R.Herrington (Solar Energy Res. Inst., Golden, CO, USA).
Scanning Electron Microsc. (USA), pt.3, p.1077-82 (1982).
Thin and thick films of materials such as CdTe, InP, Zn_3P_2, GaAs and $CuInSe_2$ represent candidate materials for low cost photovoltaic applications. The films typically exhibit a high degree of surface roughness when prepared by potentially low cost techniques. WDS and EDS analysis on an automated electron microprobe has been developed for compositional analysis of candidate films. The use of a defocused beam and low beam voltage greatly reduces the error caused by sample roughness when using standard ZAF analysis routines. Taking data from a large number of points, performing individual ZAF analysis and then averaging the results gives additional improvements in quantitative analysis. Errors due to surface roughness can easily be reduced to a few atomic percent. (7 refs.)

72.50 ACOUSTOELECTRIC EFFECTS

72453 'Current-free' amplification of hypersound in a planar configuration. E.M.Epshtein.
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1411-12 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2185-7 (Dec. 1982). [received: May 1983]
The author considers 'current-free' amplification of sound in a planar configuration when a longitudinal electric field, a magnetic field, and the wave vector of sound are all in the same plane, and the sample is open-circuited in the direction of propagation of sound, i.e. the corresponding component of the current density **j** vanishes. They consider the case when the acoustic wavelength is short compared with the mean free path of electrons and with the Larmor radius, so that one can ignore the influence of the magnetic field on the form of the integral representing collisions of phonons with electrons. (6 refs.)

72454 Dislocation theory for long-term memory in stimulated electroacoustic-echo effect in powdered piezoelectrics. A.M.Kosevich, V.V.Bogoboyashchii (Physicotech. Inst. of Low Temperatures, Acad. of Sci., Kharkov, Ukrainian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1759-64 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3110-19 (Oct. 1982). [received: April 1983]
A theory of the long-term memory is developed on the basis of a study of the motion of linear lattice defects (dislocations) under the influence of elastic and electric fields, whose behavior is described by a joint system of Maxwell's equations and the equations of the nonlinear theory of elasticity. It is shown that a periodic electric field incident on the crystal gives rise to elastic stresses whose average values over the period are sufficient to cause a noticeable redistribution of the dislocations. As a result, remanent elastic strains are created in the crystal and persist for a long time. It is found that the elastic fields of the readout pulse, which cause a shift in the natural frequency of the crystal, interact with the remanent stresses in such a way that echo signals are generated. (11 refs.)

72.55 MAGNETOACOUSTIC EFFECTS

72455 Giant quantum oscillations of sound absorption in a superlattice. G.M.Shmelev, Nguyen Hong Shon, G.I.Tsurkan (V.I. Lenin State Univ., Kishinev, USSR).
J. Phys. C (GB), vol.16, no.13, p.2587-90 (10 May 1983).
The authors demonstrate the possibility of oscillations of the electronic sound absorption in non-degenerate semiconductors with a superlattice placed in a magnetic field. The process is as follows. The Landau level is broadened so that its breadth equals the width of the lowest mini-band. Making the top of one Landau zone coincide with the bottom of another causes the resonant transition of electrons with phonon absorption to take place. This process causes large-amplitude oscillations of the absorption coefficient with changing magnetic field. (5 refs.)

72.70 NOISE PROCESSES AND PHENOMENA

72457 A fundamental noise limit for biased resistors at low temperatures. M.R.Arai (Lab. of Atomic & Solid State Phys., Cornell Univ., Ithaca, NY, USA).
Appl. Phys. Lett. (USA), vol.42, no.10, p.906-8 (15 May 1983).
A biased resistor at low temperature T is modelled by a degenerate Fermi gas whose electrons scatter from phonons in thermal equilibrium and impurities while moving in the presence of a finite electric field E. A nonperturbative solution of the Boltzmann equation valid for thin films yields a Fermi-like steady state distribution characterized by an effective temperature $T^*(>T)$. For large fields the energy scale (T^*) is set by the energy (eEl^*) absorbed in an inelastic mean free path ($l^* \propto T^{*-3/2}$). This yields T^* proportional to $E^{2/5}$. At low temperatures and frequencies the Johnson noise temperature is T^*, independent of the bath temperature for large fields. (9 refs.)

72.90 OTHER TOPICS IN ELECTRONIC TRANSPORT IN CONDENSED MATTER

72458 Analytic expression of the Warburg impedance for a rotating disk electrode. B.Tribollet, J.Newman (Dept. of Chem. Engng., Univ. of California, Berkeley, CA, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.822-4 (April 1983).
In the presence of the convective flow pattern of the rotating disk, the classical Warburg impedance is modified, particularly at low frequencies. The transformation of Scherson (1980) permits the alternating current impedance problem to be related to the transient flux-step or concentration-step behavior of the same system. Flux-step results are used to generate low and high frequency analytic expressions which overlap at intermediate frequencies. (16 refs.)

73.00 ELECTRONIC STRUCTURE AND ELECTRICAL PROPERTIES OF SURFACES, INTERFACES, AND THIN FILMS

ECOSS-5. Proceedings of the Fifth European Conference on Surface Science ... See Entry 69782

73.20 ELECTRONIC SURFACE STATES

(for emission and impact phenomena, see 79.)

72459 Electron structure of metal surfaces. S.N.Bezryadin, Yu.Kh.Vekilov, V.D.Verner, M.B.Samsonova.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.11-14 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1230-4 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors investigate the (001) and (111) surfaces of aluminum and sodium films by a method that utilizes the integral Fourier transformation. A surface state is found in aluminum film with surface (001), and resonant states are detected in films with surface (111); the electron structure of the surfaces is plotted. (17 refs.)

72460 On the nature of donor centers on the surface of an oxide cathode. A.M.Sokolov, B.P.Nikonov.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.57-60 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1278-81 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
At present it is generally agreed that an oxide cathode (OC) is in a state of dynamic equilibrium in the process of operation, such that the composition of the surface of the oxide layer (OL) is the decisive factor in the emission process, while the processes occurring in the interior of the OL and in the surface layer maintain the stability of the emission properties of the surface. There is no information regarding the part played in formation of surface donor centers by various components of OL such as barium, strontium, calcium, and oxygen, although it is precisely a particular combination of these components in a system of oxide solid solutions that gives rise to a system with unique emission properties, i.e. an oxide cathode. The authors present an investigation of oxides of alkali-earth metals (AEM) and of (BaSrCa)O oxide cathodes on both neutral bases (platinum) and on active nickel bases with deposition of 0.1% calcium (NICA) in various phases of emission activity. (7 refs.)

72461 Physical interactions between molecules and supported catalysts. J.I.Gersten (Dept. of Phys., City Coll., City Univ. of New York, New York, NY, USA).
Isr. J. Chem. (Israel), vol.22, no.4, p.408-12 (1982).
Analytic expressions for the interaction potential of a molecule with a supported catalyst are obtained. Particular attention is focused on the region of the boundary line between the metal particle and the substrate. (5 refs.)

72462 The electrostatic potential above the 100 surface plane of a FCC ionic crystal with a continuous electron charge distribution. A.B.Ephraim, M.Folman (Dept. of Chem., Technion-Israel Inst. of Technol., Haifa, Israel).
Isr. J. Chem. (Israel), vol.22, no.4, p.413-18 (1982).
The electrostatic potential above the 100 surface plane of a FCC ionic crystal has been calculated using a point charge distribution for the positive nuclei and a continuous charge density distribution for electrons. The continuous electron charge distribution has been obtained from the known results of a

Fourier crystal structure analysis. The results for the electric field and its different gradients are compared with those obtained from the Lennard-Jones and Dent model (point charge distributions for both the positive and negative ions). The two models lead to significant differences of the electrostatic potentials and their derivatives. (7 refs.)

72463 Two-dimensional electrons in a magnetic field. III. Many-body effects. Y.Shiwa, A.Isihara (Dept. of Phys., State. Univ. of New York, Buffalo, NY, USA).
Phys. Rev. B (USA), vol.27, no.8, p.4743-53 (15 April 1983).
A many-body theory is given to show that the magnetic properties of a two-dimensional electron system are dependent on the filling factor γ_0^{-1} defined as the ratio of the ideal Fermi energy against the field energy. Explicit results are obtained for absolute zero and large values of this factor. The internal energy is evaluated explicitly in consideration of the ideal, first-order exchange and ring contributions. The result converges for all r_s because for the ring contribution no small-momentum-transfer assmption is made and for low densities a rigorous analytical continuation is adopted. When plotted against γ_0^{-1}, the internal energy shows parabolic variations in a periodic way until it approaches the average kinetic energy for large γ_0^{-1}. The ideal susceptibility shows zigzag changes characteristic of absolute zero when it is plotted against γ_0^{-1}. It is zero at $\gamma_0^{-1}=2m+1$, where it jumps from $-2m$ to $2(m+1)$, m being an inverter. The Coulomb interaction suppresses the zigzag variations for small r_s and inverts the oscillating pattern at $r_s \sim 0.7$. The oscillations thereafter may be considered characteristic of a liquid state rather than a gaseous state as they are somewhat different from those for small r_s. The susceptibility is convergent for all r_s. (7 refs.)

72464 Surface states of metastable $(GaAs)_{1-x}Ge_{2x}$ alloys. A.C.Redfield, M.A.Bowen, K.E.Newman, J.D.Dow (Dept. of Phys., Univ. of Illinois, Urbana-Champaign, IL, USA).
Solid State Commun. (USA), vol.46, no.5, p.371-3 (May 1983).
The proposed order-disorder transition as x varies in metastable $(GaAs)_{1-x}Ge_{2x}$ alloys should be observable in photoemission experiments. There should be large 'kinks' in the (100) surface state energies as functions of x near the critical composition x_c. (9 refs.)

72465 Surface electronic structure of rutile-type semiconductors: $SnO_2(110)$ and $TiO_2(110)$. S.Munnix, M.Schmeits (Inst. de Phys., Univ. de Liege, Sart Tilman, Belgium).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.20-4 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The authors have investigated the electronic structure of the ideal (110) surfaces of the rutile structure compounds SnO_2 and TiO_2 using the scattering theoretic method. The results are presented in terms of surface bound states, surface resonances and wave vector resolved densities of states. For $SnO_2(110)$, the dominant features are two backbond states in the stomach gap of the main valence band and two Sn-s derived states in the lower conduction band region. For $TiO_2(110)$, they obtain no occupied surface states in the gap region, in agreement with UPS measurements on defectless $TiO_2(110)$ surfaces. The creation of the surface leads essentially to O-p resonances in the valence band region and Ti-d resonances in the conduction band region. (8 refs.)

72466 Band structure of an atom adsorbed on a surface; application to the He/Cu(113) system. J.R.Manson, G.Armand (Service de Phys. des Atomes et des Surfaces, CENS, Gif-sur-Yvette, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.681-8 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Presents a method of exactly calculating the band energies of an atom adsorbed on a surface based on Neumann iteration of the projected transition matrix equations. The band structure calculated for a model of He on a Cu(113) surface shows large shifts and band gaps and differs substantially from the nearly free particle model. Comparison with an approximate calculation shows that the contributions to the energy shifts due to continuum state transitions are nearly negligible except for the higher band levels. (9 refs.)

72467 Plasmon excitation in Al-Mg surfaces. P.Braun, M.Arias, H.Stori, F.P.Viehbock (Inst. fur Allgemeine Phys., Tech. Univ. Wien, Wien, Austria).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.714-18 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
When energetic electrons transit through solid surfaces, they lose energy in characteristic amounts. For the light metals, such as Al and Mg, collective oscillations of the electron plasma dominate over other loss mechanisms such as interband transitions. A commercial Auger spectrometer was used to analyze the surface composition and to measure the electron loss spectra of eight different samples. The electron primary energies for the electron loss spectra were 100 and 300 eV. Surface and volume plasmon energies are in good agreement with values calculated from the simple free electron model. Scribed samples, representing the bulk composition, show plasmon energies intermediate between the pure elements, with nearly linear dependence on the atomic composition. Sputtered samples exhibit a strongly altered surface composition due to preferential sputtering. Aluminum is enriched at the surface by a factor of 5. Plasmon energies observed on sputtered surfaces are generally higher, corresponding to the enrichment in aluminum. Taking into account the altered surface composition of the sputtered samples, the values of the plasmon energies fit fairly well to the values of the scribed samples. This indicates that no segregation of phases during sputtering takes place. (7 refs.)

72468 Electronic structure of the Si(111) reconstructed surface in the vacancy model. II. H.Nagayoshi (Dept. of Materials Phys., Faculty of Engng. Sci., Osaka Univ., Osaka, Japan).
Surf. Sci. (Netherlands), vol.127, no.1, p.1-9 (April 1983).
For pt.I see ibid., vol.116, p.163 (1982). The electronic structure of a 2×2 superlattice of vacancies on the Si(111) surface is examined by the self-consistent pseudopotential method. The results, together with previous work on the $\sqrt{3} \times \sqrt{3}$ structure, show that there is a large dispersion in the surface state energy bands associated with the dangling bonds toward the vacancy. This fact suggests that the surface electronic structure in the vacancy model for the 7×7 reconstructed surface is sensitive to the arrangement of vacancies. Next the three-vacancy unit model proposed by Ino (1980) for the 7×7 surface is investigated in the parametrized tight-binding scheme with the parameter values determined from the fitting of energy levels of the periodic 2×2 system to the results of the self-consistent calculation. 73.25 SURFACE CONDUCTIVITY

72469 Influence of nonlinear effects on the surface impedance of a conductor. A.P.Kopasov, A.G.Skoryukov (Gor'kii Physicotech. Res. Inst., Gor'kii, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.334-41 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.607-19 (Aug. 1982). [received: May 1983]
The influence of the nonlinear effects on the surface impedance of a conductor located in a constant magnetic field **H** oriented parallel to its surface is investigated in the case when the skin effect has the anomalous character. It is assumed that the time taken by an electron to traverse the skin layer is much shorter than the mean free time and the period of the electromagnetic wave. The reflection of the electrons by the surface is considered to be nearly diffuse scattering. The corrections to the surface impedance that stem from the following nonlinear currents are estimated: the current that is cubic in the field of the fundamental wave (the first harmonic), the current produced by the fields of the first and second harmonics together, and the current produced by the electric field of the first harmonic and the magnetic field of the rectified radioelectric current. Normally, all the three corrections are of the same order of magnitude. In certain cases the influence of the homogeneous magnetic field produced in the interior of the sample by the radio-electric current predominates. The nonlinearity can be significant even when the magnetic field of the wave is much weaker than the field **H**. (17 refs.)

72470 Conduction of two-dimensional systems with dielectric inclusions. L.V.Gorodzha, Yu.P.Emets, S.I.Stril'ko.
Tekh. Elektrodin. (USSR), no.2, p.3-6 (March-April 1983). In Russian.
An examination is made of the problem of change in effective conductivity of periodically-nonuniform media during change in the concentration of dielectric inclusions. Analytically and with the aid of physical modelling it is shown that near the metal-dielectric transition, the logarithmic variation in dependency is associated with the presence of 'tapers' in the form of inclusions. The differential conductivity of two-dimensional heterogeneous media at the critical point assumes an infinite value. (2 refs.) *A.J.B.*

73.30 SURFACE DOUBLE LAYERS, SCHOTTKY BARRIERS, AND WORK FUNCTIONS

72471 Modification of Schottky barriers in silicon by reactive ion etching with NF_3. S.Ashok, T.P.Chow, B.J.Baliga (General Electric Corporate Res. & Dev., Schenectady, NY, USA).
Appl. Phys. Lett. (USA), vol.42, no.8, p.687-9 (15 April 1983).
Reactive ion etching of silicon with NF_3 gas has been found to alter the silicon surface such that the Schottky barrier height is systematically changed with ion energy. The energetic ions introduce a net positive surface charge which increases the barrier height on *p*-Si and decreases it on *n*-Si. The Schottky barrier modification is found to be a function of ion energy as well as gas plasma used. (17 refs.)

72472 Electron work function and donor-acceptor properties of nonideal or adparticle-covered metal surfaces. L.A.Rudnitskii (State Res. & Design Inst. for Nitrogen Industry & for Products of Organic Synthesis, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.20-6 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1240-6 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Local variations of the surface potential discontinuity of nonideal or monocrystalline but adparticle-covered surfaces are described by the method of localized orbits of surface atoms, each of which is assigned a local value of the orbital electronegativity x equal to the derivative of the energy of the orbital with respect to this charge. (15 refs.)

72473 Effect of point defects of metal surface on the electron work function. A.I.Reznik, N.V.Rudenko (Kazakh State Univ., Kazakh, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.61-6 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.,* vol.46, no.7, p.1282-7 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors offer a quantitative examination of the effect of surface point defects (intrinsic adatoms and surface vacancies) on the work function of a metal. They also determine the magnitudes of the dipole moments localized on surface defects. (9 refs.)

72474 Temperature dependence of work function of principal faces of molybdenum. D.Kh.Azizova, N.A.Gorbatyi, A.F.Chumachenko (Lenin Tashkent State Univ., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.71-3 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.,* vol.46, no.7, p.1292-4 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors determine the temperature coefficient of the work function (TCWF) of the principal (110), (100) and (111) faces of Mo single crystal in the temperature range 1400-2000K. They have employed the procedure for determining the temperature shift of the break point of the delay curves that was developed by Shelton (1957). (4 refs.)

72475 Structure of potential near a nonuniform surface and the anomalous Schottky effect. S.G.Dmitriev (Inst. of Radio Engng. & Electronics, Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.98-101 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.,* vol.46, no.7, p.1320-3 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The author considers the surface potential structure and the anomalous Schottky effect in the case of practical importance of a 'spotty' surface with low concentration of 'spots' $R \gg \rho_0$, where R is the mean distance between spots and ρ_0 is their radius, but with a greatly reduced WF: $\Delta\phi \gg kT/e$, whre k is Boltzmann's constant and T is the temperature. (7 refs.)

72476 On the extraction of surface barrier potentials from threshold effects in LEED: saturation on Cu(001) revisited. G.Gaubert, R.Baudoing, Y.Gauthier (Groupe d'Etude des Surfaces, Univ. Sci. et Medicale de Grenoble, Grenoble, France), J.C.Le Bosse, J.Lopez.
J. Phys. C (GB), vol.16, no.13, p.2625-33 (10 May 1983).
The authors give a critical discussion of the extraction of the surface barrier potentials from LEED threshold effects as introduced by Dietz, McRae and Campbell (1980) for Cu(001). They show that their approximation, together with experimental and theoretical procedure, introduce an effective phase for the total-internal-reflection coefficient at the barrier from which the correct barrier shape cannot be extracted. Without the trick of a discontinuous barrier shape, the authors' correct analysis gives a better description than the empirical analysis. There remains, however, some discrepancy and the extraction of the Cu(001) barrier shape still needs both more experimental data and more theoretical studies for which the authors have specified the LEED framework. 72477 Size effect on contact resistance and device scaling. S.S.Cohen, G.Gildenblat, D.M.Brown (Corporate Res. & Dev., General Electric Co., Schenectady, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.978-80 (April 1983).
The authors have measured the size effect on the contact resistance (R_c) to shallow junctions in silicon utilizing two different metallization systems. $R_c(W)$, where W stands for the contact widths, is found to display a nonquadratic dependence. Thus, the experimental observations show that the commonly used device scaling theory which assumes that contact impedance increases inversely with the square of the scaling factor is incorrect. (9 refs.)

72478 Characteristics of the current flow and of the photoelectric properties of *p-i-n* structures made of epitaxial GaAs:Cr. M.S.Saidov, B.Sadaev, V.V.Nikitin, A.S.Saidov, G.N.Kovardakova (S.V. Starodubtsev Physicotech. Inst., Acad. of Sci., Tashkent, Uzbek SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1398-400 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR),* vol.16, no.12, p.2167-70 (Dec. 1982). [received: May 1983]
The authors report the results of an investigation of epitaxial p-i-n structures made of GaAs:Cr and exhibiting S-type current-voltage characteristics. Special features of these structures were a 'high' current responsivity and the deformation of the spectral characteristics under forward bias conditions, as well as external control (by optical excitation) of the turnover voltage and of the minimum. The structure bases were grown specially by the method of liquid epitaxy with controlled compensation of the residual donors by deep chromium acceptor levels. (19 refs.)

72479 The role of nonresonant tunnelling in contact electrification. J.Lowell (Joint Lab. of Phys. & Electrical Engng., Univ. of Manchester Inst. of Sci. & Technol., Manchester, England).
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.141-4
Tunnelling to insulator states whose energy is higher than the metal Fermi level may occur during separation of the contacting surfaces of a metal and an insulator. However, the tunnelling probability for states significantly higher than E_F is too low for this process to be important in contact electrification. (2 refs.)

(see also 74.50 in superconductors)

72480 Quantum theory of tunnelling. W.E.Hagston (Dept. of Phys., Univ. of Hull, Hull, England).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K85-9 (1 April 1983).
Recently the authors have treated various aspects of tunnelling in terms of the density matrix approach (1981, 1982). It is clear from the latter that in a formalism based on the Schrodinger equation the junction itself is not given a proper dynamical description. In order to appreciate the possible implications this could have, the authors consider the classic one-dimensional problem of a free particle of energy E_i and mass m, tunnelling through a rectangular barrier of height V_o and width d situated at the origin. The description of the barrier in terms of V_o alone is incomplete from the density matrix viewpoint, but carries with it the implicit assumption that the barrier is in contact with a large (technically infinite) energy source. As a result the energy of the tunnelling particle could be changed due to fluctuations in the barrier region. (3 refs.)

72481 Temperature dependence of interface recombination and radiative recombination in (Al, Ga)As heterostructures. G.W.'t Hooft, C.van Opdorp (Philips Res. Labs., Eindhoven, Netherlands).
Appl. Phys. Lett. (USA), vol.42, no.9, p.813-15 (1 May 1983).
From measurements of the quantum efficiency of $Al_{0.12}Ga_{0.88}As$-$Al_{0.47}Ga_{0.53}As$ double heterostructures the effective nonradiative carrier lifetime in the active region and at its interfaces is determined. From the dependence of this lifetime on active layer thickness a value for the interface recombination velocity s is obtained. For a particular sample grown by liquid phase epitaxy s turned out to be 1050 cm/s at 300K; between 110 and 360K the interface recombination velocity is proportional to $\exp(-E_a/kT)$ with an activation energy E_a of 27 meV. In the analysis the radiative coefficient B is taken to be proportional to $T^{-1.5}$, as theory predicts when a k-selection rule holds. This behaviour of B was verified experimentally with temperature-dependent minority-carrier lifetime measurements. (13 refs.)

72482 Electrical measurements on n^+-GaAs-undoped $Ga_{0.6}Al_{0.4}As$-n-GaAs capacitors. P.M.Solomon, T.W.Hickmott (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA), H.Morkoc, R.Fischer.
Appl. Phys. Lett. (USA), vol.42, no.9, p.821-3 (1 May 1983).
Current versus voltage (*I-V*) and capacitance versus voltage (*C-V*) characteristics have been measured for n^+-GaAs-undoped $Ga_{0.6}Al_{0.4}As$-GaAs capacitors over a temperature range of 80-350K. At low temperatures the structure behaves like a semiconductor-insulator-semiconductor diode with interface barrier heights of 0.38 and 0.40 eV for the bottom and top interfaces, respectively. The *I-V* curves exhibit a rectifying behavior due to the formation of a substrate depletion layer, and the *C-V* curves show the formation of the depletion layer under reverse bias as well as an accumulation layer containing $>10^{12}$ electrons/cm^2, in forward bias. The *C-V* curves agree closely with standard theory for SIS structures assuming Fermi-Dirac statistics for electrons in the accumulation layer, within an unaccounted-for voltage shift of 0.16 V. (12 refs.)

72483 Investigation into nature of low-voltage breakdown of silicon p-n junctions. O.S.Frolov, S.P.Fabrikov, V.I.Palamarchuk.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.48-51 (1982). In Russian.
The nature of the over-currents in silicon planar n^+-p junctions is investigated. By studying n^+-p junctions with a controlling gate it is possible to separate the junction currents and the currents in the MOS structure. The basic mechanism for the generation of over-currents is shown to be the thermal generation of charge carriers in local regions of the silicon. The activation energy of this process is several times smaller than the halfwidth of the forbidden zone of the silicon. The local regions of increased thermal generation are located along the perimeter of the junction and, in smaller numbers, in the MOS structure of the controlling electrode but there are hardly any in the main body of the junction. The experimental data are analysed from the point of view of the distribution through a silicon plate of rapidly-diffusing impurities and the precipitation of the impurities in the silicon surface defects. (3 refs.) *L.M.H.*

72484 High-resolution mapping of p-n junctions by computer processed EBIC signals. H.K.Schink, H.Rehme (Forschungslab., Siemens AG, Munchen, Germany).
Electron. Lett. (GB), vol.19, no.10, p.385-5 (12 May 1983).
An SEM experimental set-up is described which uses, an electron beam induced current (EBIC) technique to measure two-dimensional potential and doping distributions of p-n junctions. Computer processing is introduced to increase resolution in EBIC measurements and make the method applicable to integrated circuits. (5 refs.)

72485 About the transfer of the current of majority carriers at the absence of drift field when the avalanche local breakdown of the p-n junction develops. B.A.Krasyuk, E.E.Pakhomov, V.N.Strizhevskii.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.115-19 (1983). In Russian.
It is shown that in VHF planar silicon transistors in the quasi-neutral vicinity of the region of local avalanche breakdown of the *p-n* junction pairs of majority carriers (by electric charge) may be formed so that one carrier has a positive and the other a negative effective mass. Such pairs flow without

scattering along the *p-n* junctions in the quasi-neutral base, so that it is possible to describe the superfluid flow of these pairs at room temperature. (7 refs.)

72486 The influence of parameter nonuniformity on the two-dimensional Einstein relation in periodic and non-periodic semiconductor structures. D.Tjapkin, V.Milanovic (Inst. of Phys., Univ. of Belgrade, Belgrade, Yugoslavia).
Phys. Status Solidi b (Germany), vol.116, no.2, p.653-8 (1 April 1983).
Taking into account the fact that the effective mass of carriers is spatial dependent, the expression for the Einstein relation (the diffusion coefficient to mobility ratio) are derived for the two-dimensional electron gas. The derived expressions are general and do not assume exclusively the parabolic dependence of the carrier energy on the wave vector, as well as the case of the quantum limit. The numerical results are given for GaAs-Al$_x$Ga$_{1-x}$As superlattice structure assuming that the dependence of the potential energy is rectangular. The maximum and the minimum are found for D/μ versus N_s which could be explained as a consequence of the spatial dependence of effective mass. (8 refs.)

72487 Microscopic investigations of semiconductor interfaces. G.Margaritondo (Dept. of Phys., Univ. of Wisconsin, Madison, WI, USA).
Solid-State Electron. (GB), vol.26, no.6, p.499-513 (June 1983).
The author reviews the results obtained in recent years by applying surface-sensitive experimental techniques to the study of metal-semiconductor and semiconductor-semiconductor interfaces. The review starts with a short discussion of the most widely used experimental probes. Then the initial impact of this new approach on the old theoretical concepts about semiconductor interfaces is discussed. A presentation of selected results follows, including the detection of interface states, the formulation of the defect model, the discovery of chemical trends in the interface parameters and the recent progress in understanding heterojunction discontinuities. The review is concluded by a discussion of the open problems and of the most likely future developments in this field. (84 refs.)

72488 Photosensitivity spectra of a nonideal *p*-Si-*n*-GaAs heterojunction. A.G.Denisov, G.S.Dordzhin, Yu.G.Sadof'ev, L.V.Sharonova, A.Ya.Shik, Yu.V.Shmartsev (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1386-90 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2152-7 (Dec. 1982). [received: May 1983]
An investigation was made of the spectral dependences of the photoresponse of *p*-Si-*n*-GaAs heterojunctions prepared by the molecular beam epitaxy method. It was found that the form of these spectral dependences was a function of the parameters of the heterojunction structure and of the illumination conditions. In the case of structures with low-resistivity GaAs films the photoresponse spectrum was a wide band and it was not very sensitive to the illumination conditions. In the case of films of higher resistivity the spectrum had a sharp peak at $\hbar\omega \approx 1.1$-1.2 eV of relative amplitude which increased rapidly as the illuminated spot moved away from the contact. This peak was of the same origin as the usual short-wavelength fall of the photoconductivity of a semiconductor and it was associated with the diffusion of nonequilibrium carriers along a nonideal heterojunction interface with a high concentration of recombination centers. A rigorous quantitative theory of the photoresponse of a nonideal heterojunction was developed and compared with the experimental results. (13 refs.)

72489 Theory of galvanomagnetic effects in supperlattices. V.M.Genkin, E.S.Potapenko (Inst. of Appl. Phys., Acad. of Sci., Gorki, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1441-3 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2225-8 (Dec. 1982). [received: May 1983]
The authors present a theory of the galvanomagnetic effects in semiconductor superlattices. They consider an asymmetric superlattice in crossed electric and magnetic fields, and assume that H lies in the plane of the conducting layers, whereas the field E is normal to the layers (parallel to the superlattice axis). (7 refs.)

72490 Amplification and reversal of a soliton electric current in a superlattice by an external magnetic field. E.M.Epshtein.
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1445 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2231-3 (Dec. 1982). [received: May 1983]
The nonlinearity of the electron properties of a semiconductor superlattice enables propagation of electromagnetic solitons. The author shows that this effect may be amplified and its sign may be reversed by the application of an external magnetic field prependicular to the superlattice axis. They consider solitons traveling at right-angles to the superlattice axis (i.e. along the layers forming the superlattice), so that the electric field of a soliton is directed along and the magnetic field across the superlattice axis. They assume that the x axis is parallel to the electric field, the y axis is parallel to the magnetic field, and the z axis is parallel to the direction of propagation of a soliton. (4 refs.)

72491 Peculiarities of the current transmission in degenerate semiconductor-semiconductor heterojunctions. S.Yu.Pavelets, T.M.Svanidze, V.P.Tarasenko.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.581-5 (April 1983). In Russian.
Studies peculiarities of the direct current in degenerate semiconductor-semiconductor *p-n*-heterojunctions. Strong degeneration of copper sulphide permits a considerable increase in the diffusion potential of Cu$_{1.8}$S-CdS(CdSe) heterojunctions and for GaAs and InP this results in formation of inverse *p-n* junctions in them. In all investigated heterojunctions recombination-tunnel currents dominate whose character is dependent on the environmental conditions. The current transmission-semiconnection contact is featured by an interconnection of the carrier recombination and generation in the space charge region with tunnelling. (12 refs.)

72493 Relation between current-voltage characteristics and interface states at metal-semiconductor interfaces. C.Barret (Inst. d'Electronique Fondamentale, Univ. Paris-Sud, Orsay, France), P.Muret.
Appl. Phys. Lett. (USA), vol.42, no.10, p.890-2 (15 May 1983).
In the case of metal-covalent semiconductor interfaces, the 'pinning' of the metal Fermi level was attributed to large densities of interface states by Bardeen, 35 years ago. These interface states are usually thought to be in equilibrium with the metal. But capacitance measurements show unambiguously the existence of states in equilibrium with the semicondcutor, even for cleaved contacts. Freeouf argued recently that this kind of states would influence *I-V* characteristics. Here, some examples of such a correlation between interface states spectra and *I-V* nonidealities are presented for Au-InP and Au-Si contacts. (14 refs.)

72494 A note on work function of metal-insulator system. K.F.Wojciechowski (Inst. of Experimental Phys., Univ. of Wroclaw, Wroclaw, Poland).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.575-8 (April 1983).
The work function ψ of a metal-insulator system is calculated for a simple model of the system, in which the metal is replaced by jellium and the insulator by a continuum with a static dielectric constant ϵ. The gradient expansion of the kinetic, exchange and correlation contributions to the work function is taken into account. The calculated work functions for different metal-insulator systems have a minimum at the value $\epsilon \sim 2$, contrary to previous calculations which neglect gradient expansion and give the minimum of ψ at $\epsilon \sim 8$. (10 refs.)

72495 Formation of electron structure of (111) Si-Au boundary. V.K.Adamchuk, S.I.Fedoseenko, A.M.Shikin (Leningrad State Univ., Leningrad, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.105-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1328-31 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Presents some results of a comparative study of the initial phases of formation of (111) Si-Au (with gold deposited onto a pure (111) surface of Si) and (111) Si/C-Au (with gold deposited onto a carbon-passivated silicon surface) interphase boundaries, by the methods of Auger electron spectroscopy (AES) and characteristic-loss spectroscopy (CLS). (9 refs.)

72496 The effects of deep levels in GaAs MESFETs. A.Zylbersztejn (Div. Composants Microondes, Thomson-CSF, Orsay, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.44-9 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The electrical characteristics of a GaAs MESFET are shown to be variously affected by deep levels, depending on their location in the gap and where they are in the device. An appropriate variation of the DLTS technique can be used to characterize deep levels in a MESFET. Measurements performend at emission time constants down to 0.6 ns have permitted a quantitative study of microwave noise due to electron traps in the channel. A spurious backgating effect in GaAs integrated circuits is due to hole traps on the substrate side of the active layer-substrate interface. The free surface of GaAs MESFETs is usually depleted due to the presence of surface states. Their charge state can be modified by lateral carrier transport on the GaAs surface, which affects the device electrical performances. (34 refs.)

72497 Characterization of the interface states at Al-GaAs Schottky barriers with a thin interface layer. J.R.Morante, A.Lousa, J.E.Carceller, J.L.Morenza (Dept. d'Electricitat i Electronica, Univ. de Barcelona, Barcelona, Spain).
Solid-State Electron. (GB), vol.26, no.6, p.537-8 (June 1983).
The interface states density in GaAs Schottky diodes with a thin interface layer is found to be the origin of the capacitance values deviation with respect to the values deduced from the Mott-Schottky law. The dependence of this deviation versus the frequency and the forward applied bias is justified on the basis of a quasi-constant energy distribution of the interface states. (7 refs.)

72498 Schottky barrier height variation with metallurgical reactions in aluminum-titanium-gallium arsenide contacts. Y.Wada, K.Chino (Musashino Electrical Communication Lab., Nippon Telegraph & Telephone Public Corp., Tokyo, Japan).
Solid-State Electron. (GB), vol.26, no.6, p.559-64 (June 1983).
The behaviour of Al/Ti/*n*-GaAs Schottky contacts under heat treatment at around 400°C have been studied for their application to GaAs MESFETs. Barrier heights have been determined using both *I-V* and *C-V* measurements as a function of heat treatment time. Reaction products due to heat treatment have been studied by X-ray diffraction and Auger electron spectroscopy. The Al/Ti/*n*-GaAs Schottky contacts barrier height shows an '*N*'-shaped variation in response to heat treatment time. A marked reduction in barrier height follows a slight increase at the initial annealing stage. The barrier height then takes a minimum value. The slight increase in barrier height at the initial

stage in the heat treatment is brought about by a Ti and GaAs reaction. The marked barrier height reduction is closely correlated to formation of the compound Al_3Ti. The increase in barrier height observed after the reduction can be explained in terms of GaAlAs formation at the metal-semiconductor interface. This seems to indicate that heat treatment is essential for application of Al/Ti/*n*-GaAs Schottky contacts to practical devices. (13 refs.)

72499 Study of Ag/Si(111) submonolayer interface. I. Electronic structure by angle-resolved UPS. T.Yokotsuka, S.Kono, S.Suzuki, T.Sagawa (Dept. of Phys., Faculty of Sci., Tohoku Univ., Sendai, Japan).
Surf. Sci. (Netherlands), vol.127, no.1, p.35-47 (April 1983).
Angle-resolved ultraviolet photoelectron spectra have been measured for well defined Ag/Si(111) submonolayer interfaces of (1) Si(111)($\sqrt{3}\times\sqrt{3}$)R30°-Ag, (2) 'Si(111)(6×1)-Ag', and (3) Ag/Si(111) as deposited at room temperature. Non-dispersive and very narrow (FWHM~0.4-0.5 eV) Ag 4d derived peaks are found at 5.6 and 6.5 eV below the Fermi level for surface (1) and at 5.3 and 6.0 eV for surface (2). Dispersions of sp 'binding' states in the energy range between E_F and Ag 4d states have been precisely determined for surface (1). Electronic structures similar to those of the Ag(111) surface, including the surface state near E_F, have been observed for surface (3). (21 refs.)

72500 Hot-electron thermo-EMF in silicon. S.P.Ashmontas, L.L.Vingyalis, L.E.Subachyus (Inst. of Semiconductor Phys., Acad. of Sci., Vilnius, Lithuanian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1361-4 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2110-15 (Dec. 1982). [received: May 1983]
The field and carrier-density dependences of the contact potential U_c were determined for a contact between a metal and silicon with an n-n^+ junction subjected to 3-cm microwave radiation. It was found that on reduction in the electron density in the *n*-type region the value of U_c/E_m^2 increased both at T_0=300K and at T_0=80K (E_m is the microwave field amplitude). Phenomenological equations for the current and heat balance in the warm-electron range were used to calculate the carrier-density dependence of U_c/E_m^2. It was found that at T_0=300K the rise of E_c/E_m^2on reduction in *n* was mainly due to an increase in the size of the active region of the n-n^+ junction, where a strong microwave electric field was established, and also due to an increase in the contribution of the microwave signal rectification. At T_0=80K the main contribution to the increase in U_c/E_m^2 on reduction in *n* was due to an increase in the size of the active region of the n-n^+ junction as well as due to an increase in the mobility and phenomenological energy relaxation time of electrons. 72501 Surface charge generation on the metal-semiconductor interface. E.V.Buzaneva, V.I.Strikha, G.E.Chaika.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.575-81 (April 1983). In Russian.
A thermodynamic calculation is presented for the concentration of intrinsic and metal-induced defects on the semiconductor surface and on the metal-semiconductor interface. The calculations performed permit explaining a series of experimental dependences which have not been explained satisfactorily so far. (12 refs.)

72502 Gate-width dependence of radiation-induced interface traps in metal/SiO_2/Si devices. M.R.Chin (Westinghouse Res. & Dev. Center, Pittsburgh, PA, USA), T.P.Ma.
Appl. Phys. Lett. (USA), vol.42, no.10, p.883-4 (15 May 1983).
The density of radiation-induced interface traps in a post-metal-annealed (PMA) Al-gate metal-oxide-semiconductor (metal/SiO_2/Si) depends strongly on the linewidth of the metal gate over a wide range (1-750 μm) of linewidths studied, although there is no discernible dependence prior to the irradiation. The dependence is such that the narrower the linewidth, the fewer the radiation-induced interface traps. Such dependence has been generally observed for both *p* and *n*-type Si samples, for oxides grown in dry O_2 or steam at temperatures over a wide range (900-10000°C), and for PMA treatment either in dry N_2 or in forming gas (10% H_2+90% N_2). The results can be qualitatively explained by a model based on the gate linewidth dependence of the SiO_2/Si interfacial stress prior to irradiation, which affects the radiation sensitivity in accordance with the strained bond model. (28 refs.)

72503 Influence of characteristic sizes of inhomogeneities on C-V dependence of MOS structures. A.I.Shkrebtii, A.V.Sachenko, O.V.Snitko.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.3-8 (1982). In Russian.
A method is proposed for calculating the capacitance-voltage dependences of MOS structures taking into account inhomogeneities of the following types: the semiconductor-dielectric interface relief; a charge nonuniformly incorporated into the dielectric and a nonuniformity in the volumetric doping level. The distribution of the electrostatic potential, electrons and holes in the surface region of the surface charge of the semiconductor is found in a low-signal amplitude-based approximation of the inhomogeneities. The part played by the magnitude of the characteristic size of the inhomogeneity in the capacitance-voltage characteristics is analysed. Inhomogeneities with a characteristic size less than or of the order of the effective screening length are found to cause a rise in the capacitance and an increase in the slope of the capacitance-voltage characteristics whereas inhomogeneities with a characteristic size considerably greater than the effective screening length produce a reduction in the slope of the capacitance-voltage characteristics. (4 refs.) *L.M.H.*

72504 Study of InSb-based EOS and MOS structures. O.V.Romanov, S.G.Sazonov, N.V.Motaleva, M.A.Sokolov.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.32-6 (1982). In Russian.
The complex field effect in electrolytes is used to demonstrate the feasibility of effective control of the parameters of a growing dielectric and the dielectric-semiconductor boundary, formed during anode oxidation. The different factors in the growth of the dielectric and in the subsequent processing of the DS system based on InSb are studied as well as the MOS structures formed from them. The influence of a whole series of different parameters involved in the formation of the DS system based on InSb characterises this process as the process of the formation of a complex multiple-component heterogeneous system, the quality of which is determined by the variations in the stoichiometric composition of the anodic oxide at the interface with the semiconductor. (5 refs.) *L.M.H.*

72505 Determining surface state spectrum from measurements of steepness of transfer characteristics of MOS transistor at high and low frequencies. Yu.S.Zharkikh, S.V.Lysochenko.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.36-45 (1982). In Russian.
A method is proposed for determining the density of the surface states overloaded during inversion bending of the zones on the surface of the semiconductor in metal-oxide-semiconductor (MOS) structures. The method is based on measuring the steepness of the transfer characteristics of a transistor at high and low frequencies. The possibilities of the method are analysed. The influence of inhomogeneities on the measurement results is discussed and an experimental investigation is made into the SS spectra in silicon MOS structures. The influence of γ-irradiation on the SS density at the edge of the forbidden zone is studied. No specially-designed test structures are required for the application of the method, which will clearly be extremely useful in the processing of new MOS structure technology. (9 refs.) *L.M.H.*

72506 Influence of irradiation temperature on radiative processes in MOS structures. V.I.Girii, S.I.Kornyushin, V.I.Shakhovtsov, L.G.Shchegoleva.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.78-81 (1982). In Russian.
The influence of gamma irradiation at temperatures ranging from 77 to 300K on the basic parameters of MOS structures—the charge in the dielectric, the surface state density and the effective charge-carrier mobility in the inversion channels μ_s is examined. Irradiation at 77K is shown to lead to the incorporation into the SiO_2 film of an additional positive charge without any change in the surface state density and to a rise in μ_s. These effects disappear when the structures are heated to room temperature. Physical mechanisms describing the experimental results obtained are proposed. (9 refs.) *L.M.H.*

72507 Electrochemical methods of forming DS structures and electrophysical properties of electrolyte-dielectric-semiconductor systems. P.P.Konorov.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.81-92 (1982). In Russian.
A survey is given of methods of forming dielectric layers on the surface of semiconductors by means of electrochemical oxidation and also of methods of achieving a directional change in the properties of dielectric-semiconductor (DS) structures by polarising them in electrolytes. The specific peculiarities of the electrolyte-dielectric-semiconductor system, which are at the root of the electrochemical oxidation and directional change in the properties of the DS structures, are described. The mechanisms for these processes are considered and the characteristics of DS structures produced electrochemically are presented. Particular attention is paid to DS structures based on silicon and semiconductors of the A^{III}-B^V group. (93 refs.) *L.M.H.*

72508 Electron beam induced damage in poly-Si gate MOS structures and its effect on long-term stability. M.Shimaya, N.Shiono, O.Nakajima, C.Hashimoto, Y.Sakakibara (Musashino Electrical Communication Lab., NTT Public Corp., Musashino-shi, Tokyo, Japan).
J. Electrochem. Soc. (USA), vol.130, no.4, p.945-50 (April 1983).
Repeated electron beam irradiation and annealing processes are shown to enhance radiation damage in the gate SiO_2, compared to only one irradiation and annealing cycle. Repeated irradiation with 20 keV electrons causes an introduction of more positive charge, neutral traps, and interface traps. Neutral trap density gradually increases with increasing repeated cycles, even after 700°C annealing in dry N_2, though these traps are removed completely by only one cycle. Positively charged and neutral traps are determined by avalanche hot-electron injection, and interface traps at the SiO_2-Si interface are determined by quasistatic C-V measurements. Long-term stability for electron beam irradiated MOS capacitors has been examined through positive and negative bias-temperature (BT) stress aging. Devices annealed at 450° and 700°C result in faster and larger V_{FB} shifts and interface trap generation under BT stress than those for devices annealed at 1000°C. Around 1000°C annealing is found necessary to completely remove structural defects in the oxides induced by ionizing radiation and to assure good long-term stability for MOS devices fabricated by electron beam lithography. (23 refs.)

72509 The properties of ZnSe MIS structure. H.Ozaki, M.Furukoshi.
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.77-82 (1982). In Japanese.
An insulating layer of Al_2O_3 is deposited on ZnSe substrate by electron beam evaporation, and MIS structure of Au-Al_2O_3-ZnSe fabricated. The properties of the MIS structure are investigated by photoluminescence, electroluminescence and current-voltage characteristics. Under low forward-bias, the MIS device shows blue (2.67 eV) and orange (2.0 eV) electroluminescence at room temperature. (16 refs.)

72510 Accumulation and discharging of the hole charge in oxide layers of MIS structures. E.V.Anufriev, V.A.Gurtov (Petrozavodsk State Univ., Petrozavodsk, USSR).
Phys. Status Solidi a (Germany), vol.76, no.1, p.107-11 (16 March 1983).
Charge accumulation of non-equilibrium holes induced by X-ray irradiation is studied in silicon oxide layers of MIS structures. Thermal silicon dioxides obtained by oxidation in dry oxygen using chlorine technique as well as an anodic silicon dioxide are used as gate dielectrics. In all cases accumulation of approximately the same number of positively charged centers occurred after an X-ray exposure. Activation energy of isothermal annealing process is estimated as (0.2 to 0.5) eV. (11 refs.)

72511 Influence of backside argon implantation on the Si-SiO_2 interface. J.Dziesiaty (Sektion Phys., Humboldt-Univ. zu Berlin, Berlin, Germany), F.-G.Kirscht, M.Mai, K.-R.Sprung.
Phys. Status Solidi a (Germany), vol.76, no.2, p.K105-8 (16 April 1983).
Investigates whether a backside argon implantation shows an influence on the defect density and the generation lifetime of minority carriers near the surface of the water after more than one high-temperature step. (8 refs.)

72512 Characteristics of formation and annealing of defects in silicon near the Si-SiO_2 interface during implantation of Ar^+ions. G.N.Galkin, R.U.Abbasova, E.A.Bobrova, V.S.Vavilov (P.N. Lebedev Phys. Inst., Acad. of Sci., Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1390-3 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2158-61 (Dec. 1982). [received: May 1983]
The method of low-frequency capacitance voltage characteristics of metal-insulator-semiconductor structures was used to study defects in silicon created by the implantation of Ar^+ ions in the vicinity of the Si-SiO_2 interface (dose

range 3×10^{10}-10^{12} ions/cm^2), which was followed by annealing at temperatures from room to 800°C. spectra of the density of the surface states of Si-SiO$_2$ structures were used to find the energy levels of defects at $E_c-0.28$, $E_c-0.40$, $E_v+0.44$, $E_v+0.36$, and $E_v+0.26$ eV, which were observed earlier after the implantation of Si$^+$ ions in an Si-SiO$_2$ structure. The thermal stability and the numbers of some of these defects differed for the implantation of Ar$^+$and Si$^+$. A characteristic defect formed as a result of implantation of Ar$^+$ had an energy level near the middle of the band gap, observed earlier after annealing at 500 and 700°C; this defect was found between 300 and 700°C. An analysis was made of the possible nature of defects formed as a result of implantation of Ar$^+$ions. (7 refs.)

72513 Luminescence of metal-tunnel-thin insulator-n-Si-p$^+$-Si systems. B.A.Malakhov (Inst. of Radio Engng. & Electronics, Acad. of Sci., Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1406-7 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2178-80 (Dec. 1982). [received: May 1983]
Luminescence was observed for a metal-tunnel-thin insulator-n-Si-p$^+$-Si system. The emission of luminescence can be explained by the recombination of electrons and holes at the semiconductor-insulator interface where a p-type inversion layer forms in the low-resistance state. When the voltage drop across the insulator is sufficiently high, the tunneling of electrons from the metal to the direct silicon band (point Γ_{15}) takes place and this is followed by radiative recombination. A similar situation may be realized in a metal-tunnel-thin insulator-p$^+$-Si system. Systems of this kind also emitted luminescence when a negative voltage in excess of 4 V was applied to the metal. No luminescence was emitted when a positive bias voltage was applied to the metal electrode. Moreover, luminescence was not observed in the case of a metal-tunnel-thin insulator-n$^+$-Si system. 72514 Electrical conduction and switching mechanism in Bi$_2$O$_3$ thin film diodes. Young-Kwon Sung, Nam-Ki Min, Ju-Ik Lee.
Trans. Korean Inst. Electr. Eng., vol.31, no.12, p.180-7 (1982). In Korean.
The electrical properties of metal-Bi$_2$O$_3$-metal diodes have been investigated. The DC current-voltage characteristic is ohmic at low voltage, followed by a square law region which suggests a space charge limited current, finally shows current-controlled negative resistance (CCNR). The occurrence CCNR is explained by the mechanism for setting up space charge which would result in a field redistribution and lead to the increased generation, injection or multiplication of carriers. The AC current-voltage characteristics are different from the DC I-V characteristics, and it doesn't appear the space charge effect vividly. Especially switching phenomena are observed in Ag-Bi$_2$O$_3$-Ag diodes and its behavior may be explained by Ag filamentary model. (15 refs.)

72515 Test of short range effects in surface enhanced Raman spectroscopy: an elastic tunnelling study of pyridine-metal interfaces. J.L.Tomlin, D.G.Walmsley, R.J.Turner, N.M.D.Brown (School of Phys. Sci., New Univ. of Ulster, Coleraine, N Ireland).
Surf. Sci. (Netherlands), vol.127, no.2, p.331-46 (April 1983).
The elastic tunnel current versus bias over the range ±1 V in junction of the type Al-I(X)-M where M=Pb, Ag, Cu or Au and X is 2-, 3- or 4-pyridinecarboxaldehyde has been used to determine parameters which describe the barrier in each. Little variation attributable to the different dopants is observed but there are substantial effects attributable to the top metal M in both clean and doped junctions. It is suggested that electron densities of states are responsible. The potential step between dopant and metal M decreases in the sequence Au:Pb:Ag. Evidence is collated from a number of sources to suggest that hydroxyl dipole layers influence the metal-organic interface potential step both in aqueous-solution-doped tunnel junctions and in SERS systems. 72516 Switching and negative capacitance in Al-Ge$_{15}$Te$_{81}$Sb$_2$S$_2$-Al devices. G.S.Nadkarni, N.Sankarraman, S.Radharkrishnan (Dept. of Phys., Inst. of Sci. Bombay, India).
J. Phys. D (GB), vol.16, no.5, p.897-908 (14 May 1983).
A theory to explain the switching behaviour and variation of the capacitance with temperature and voltage, is proposed for vacuum evaporated metal-glass-metal devices. It is also shown that the observed capacitance of the device could be negative under voltage bias conditions. It is proposed that the voltage V_{th} at which the device changes from the off state to the on state and the transition voltage V_{cn} at which the capacitance of the device becomes negative should be related to the glass transition temperature T_g. A study of Al-Ge$_{15}$Te$_{81}$Sb$_2$-Al devices reveals that the experimental results are in concurrence with the theoretical predictions. (9 refs.)

73.60 ELECTRONIC PROPERTIES OF THIN FILMS

72517 The frequency response of the effective resistance of thin palladium and manganese films. M.A.Angadi (Dept. of Phys., Univ. of the West Indies, St. Augustine, Trinidad), S.M.Shivaprasad.
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.207-9 (May 1983).
The authors' study shows the validity of the model proposed by A.A. Hirsch and S. Bazian (1964) for very thin Mn and Pd films. Though this property is strictly valid only for discontinuous films (as in Mn), it is also found to explain the phenomena in semicontinuous films (as in Pd), the simultaneous presence of different conduction processes in thin films is thus indicated. (12 refs.)

72518 Dependence of the magnetoresistance on dispersion properties of Permalloy films with allowance for the angular spatial dispersion of the anisotropy. Yu.V.Kornev, T.V.Borodina (N.E. Bauman Higher Tech. Coll., Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.472-8 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The published theory of the magnetoresistance of uniaxial films and a statistical approach are used to obtain an analytic expression for the dependence of a quantity representing the magnetoresistance on the angles of planar and spatial dispersion of the magnetic anisotropy axis, which is supported well by the experimental results on Permalloy films. This dependence may be used as the physical basis of a contactless method for the fabrication of bubble-domain memories. The method involves the use of ferromagnetic resonance and a spectrometer is suggested for this purpose. (8 refs.) *A.T.*

72519 Characteristics of the Hall effect in two-layer iron and cobalt films. I.Ya.Kudryashova, V.S.Cherkashin (Buryat Pedagogical Inst., Ulan-Ude, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.491-5 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An experimental investigation was made of the Hall effect in two-layer iron-cobalt films. The two layers were evaporated on one another or were separated by an insulating spacer. Their thicknesses were very different. A comparison of the results of measurements of the Hall e.m.f. in the case of two- and one-layer films established the degree of influence of the individual components of the conductivity tensor on the anomalous Hall coefficient, the participation of the 3d electrons in the conductivity of iron and cobalt and the sign of their polarization, and the electron coupling between the layers. (5 refs.) *A.T.*

72520 The CV product of etched aluminium anode foil. H.J.de Wit, C.Crevecoeur (Philips Res. Labs., Eindhoven, Netherlands).
J. Electrochem. Soc. (USA), vol.130, no.4, p.770-6 (April 1983).
Deals with the analysis of tunnel structures in etched aluminium foil for electrolytic capacitors. The dependence of the capacitance of such foil on anodization voltage and on frequency was measured. Electron microscopy data were also used. The product of series capacitance C_s and anodization voltage U_f shows a characteristic decrease with U_f. This behaviour is first analyzed with the model in which it is attributed to the closing of tunnels during anodization. This model, however, leads to irremediable inconsistencies and has to be abandoned. It is proposed instead that the main cause of the decrease of $C_sU_f \sim U_f$ is the fact that the oxide layers of neighboring tunnels grow against each other during anodization. Results of anodization-stripping-anodization experiments are contrary to the former and in accordance with the latter model. (5 refs.)

73.60F Semiconductor films

72521 High mobility in liquid phase epitaxial InGaAsP free of composition modulations. M.Quillec, J.L.Benchimol, S.Slempkes, H.Launois (CNET, Bagneux, France).
Appl. Phys. Lett. (USA), vol.42, no.10, p.886-7 (15 May 1983).
$In_xGa_{1-x}As_yP_{1-y}$ epilayers lattice matched to InP were grown from the liquid phase at temperatures far above the commonly used temperature range. The goal was to get off the unstable region corresponding to compositions emitting in the wavelength range of 1.2 μm$<\lambda<$1.5 μm at 650°C. $In_{0.71}Ga_{0.29}As_{0.65}P_{0.35}$ (λ=1.35 μm) layers thus grown have the highest electron Hall mobilities ever obtained in this material: $\mu_{300K}=7000$ cm^2/Vs and $\mu_{77K}=23200$ cm^2/Vs for $N_d-N_A=8.10^{14}$ cm^{-3}. The authors suggest that a contribution to mobility limitation might be related to the composition modulations present in epilayers grown in the usual temperature range. (10 refs.)

72522 Microstructure and electro-optical properties of evaporated indium-oxide films. Z.Ovadyahu, B.Ovryn, H.W.Kraner (Brookhaven Nat. Lab., Upton, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.917-21 (April 1983).
The microstructures and electro-optical properties of thermally evaporated indium-oxide films are given and discussed. It is shown that highly transparent and conducting films can be prepared at relatively low (~150°C) substrate temperatures, with and without doping by tin. Results of stoichiometry measurements in conjunction with the Hall effect and crystal structure data suggest the existence of indium atoms with different valences in these films. This implies that the conduction mechanism in this material may be more complicated than hitherto assumed. (17 refs.)

72523 Anomalous transport properties in disordered organic layers. B.Ziolkowska-Pawlak, W.Mycielski, A.Lipinski (Inst. of Phys., Tech. Univ. of Lodz, Lodz, Poland).
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.215-19 (May 1983).
The results of time-of-flight experiments for two different organic compounds, copper phthalocyanine and tetracene layers are presented. These materials were investigated in the form of vacuum evaporated layers in which, as is known, transport phenomena are more complicated in comparison with those in monocrystals. The current-time profile observed for both materials was highly dispersive as judged by the phenomenological theory of stochastic hopping or multiple-trapping processes. The differences between theoretical prediction and experimental data are demonstrated, first of all, in the field dependence of the disorder parameters α_1 and α_2 for the initial and final parts of the log i versus log t plots, respectively. The results are compared with the experimental data for other materials, as well as with the results of numerical computations given by other authors. (12 refs.)

72524 Minority carrier diffusion lengths in liquid phase epitaxial InGaAsP and InGaAs. M.M.Tashima, L.W.Cook, G.E.Stillman (Materials Res. Lab., Univ. of Illinois, Urbana, IL, USA).
J. Electron. Mater. (USA), vol.11, no.4, p.831-46 (July 1982). [received: Nov. 1982]
Minority carrier diffusion lengths were determined for InGaAsP and InGaAs layers grown by liquid phase epitaxy on (100) InP substrates by measuring the variation of the short circuit photocurrent as a focused laser beam was scanned along a beveled p-n junction. The effect of lattice-mismatch on the hole diffusion length (L_p) for n-type unintentionally doped InGaAsP layers (λ_g=1.15 μm) was investigated for mismatch values from −0.25% to

+0.31%, with the longest diffusion length occurring when the epitaxial layer was lattice-matched to the substrate. As the amount of mismatch increased, L_p decreased. Electron diffusion lengths, L_n, were determined for lattice-matched quaternary and ternary layers grown from Zn doped melts over a wide range of hole concentrations. At the lowest hole concentrations, the electron diffusion lengths were 3.5 and 2.5 μm for the quaternary and ternary, respectively. As the hole concentration increases, L_n decreased and at the highest concentration, L_n was 0.13 μm for InGaAsP and 0.83 μm for InGaAs. (16 refs.)

72525 Electric and photoelectric investigations of β-nickel phthalocyanine thin films. T.G.Abdel-Malik, A.A.Aly, A.M.Abdeen, H.M.El-Labany (Phys. Dept., Univ. of El-Minia, El-Minia, Egypt).
Phys. Status Solidi a (Germany), vol.76, no.2, p.651-9 (16 April 1983).
Electric and photoelectric measurements of β-nickel phthalocyanine films are quantitatively explained by the existence of an exponential trap distribution. An analysis of the results enables the determination of the electron mobility, density of states, total trap density, and the characteristic temperature of the trap distribution. (24 refs.)

72526 Influence of powerful electrical fields on conductivity of silicon nitride films. V.V.Bulavinov, Yu.A.Tarantov, A.P.Baraban.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.28-32 (1982). In Russian.
The change occurring in the electrophysical characteristics of silicon nitride films during the degradation of silicon-silicon nitride structures is investigated. An increase is noted in the conductivity and density of the surface states at the internal boundary of the dielectric, indicating an increase in the density of the localised states in the centre of the forbidden zone of the dielectric. The results are interpreted within the framework of a model of tunable amphoteric centre formed by a ruptured silicon bond on the surface of a silicon cluster inside silicon nitride. (11 refs.) *L.M.H.*

72527 Variations of trap states and dangling bonds in CVD Si_3N_4 layer on Si substrate by NH_3/SiH_4 ratio. S.Fujita, H.Toyoshima, M.Nishihara, A.Sasaki (Dept. of Electrical Engng., Kyoto Univ., Kyoto, Japan).
J. Electron. Mater. (USA), vol.11, no.4, p.795-812 (July 1982). [received: Nov. 1982]
This study is concerned with deep trap densities and energy levels in CVD Si_3N_4 layer deposited on Si substrates at 700°C with various gas flow ratios NH_3/SiH_4. As the ratio NH_3/SiH_4 increases from 10 to 1000, the trap density decreases from 8×10^{19} to 2×10^{19} cm^{-3}, and energetic distribution of trap states becomes lower and/or electron emission probability from trap states becomes less. The results are discussed in terms of chemical and optical propertiers of Si_3N_4 film revealed by infrared absorption, Auger electron spectroscopy, and ellipsometry. It is shown that (i) Si dangling bonds create deep trap states and (ii) O and H atoms act as terminators to decrease trap density. (27 refs.)

74.00 SUPERCONDUCTIVITY

74.10 OCCURRENCE, CRITICAL TEMPERATURE

72528 Influence of low temperature high pressure and high temperature high pressure treatment on structure and superconductivity of amorphous alloy $La_{80}Al_{20}$. Liu Zhi-yi, Zhao You-xiang, Liu Zhen-xing, Chen Gui-yu, Wang Chao-guo, Wang Shou-zheng (Inst. of Phys., Acad. Sinica, Beijing, China).
Acta Phys. Sin. (China), vol.32, no.3, p.354-9 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
The rapidly quenched $La_{80}Al_{20}$ alloy is amorphous. At atmospheric pressure, its crystallisation temperature and glass temperature are ~280°C and ~242°C respectively, according to DTA measurements. The superconducting transition temperature T_c increases from 3.87 to 4.18K, in the hydrostatic pressure range of 1-4770 bars, while its residual resistance decreases significantly. After high pressure-high temperature treatment (25 kbar, ~160°C, 40 min), amorphous→crystalline transition of $La_{80}Al_{20}$ alloy occurs, as disclosed by X-ray diffraction method. The product consists of α-La phase and a new metastable phase, and its T_c increases from 3.9 to 5.7K. (27 refs.)

72529 The empirical correlations between phonon spectrum parameters λ, ⟨ω⟩, ⟨ω²⟩ and the Hall coefficients of amorphous superconductors. Cao Xiao-wen (Inst. of Plasma Phys., Acad. Sinica, Hefei, China).
Chin. Phys. (USA), vol.3, no.1, p.23-8 (Jan.-March 1983). [received: May 1983]
It is found that there is an empirical correlation between phonon spectrum parameters λ, $\langle\omega\rangle$, $\langle\omega^2\rangle$ and the Hall coefficients R_H in a variety of non-transition metals and alloys. There is a maximum of λ, $\langle\omega\rangle$ and $\langle\omega^2\rangle$ as $R_H=-3.5--4.0\times10^{-11}$ m^3/AS. There is also a similar empirical correlation between λ, $\langle\omega\rangle$, $\langle\omega^2\rangle$ and the Hall coefficients R_{HL} for the corresponding liquid metals. Finally, the question of raising T_c of amorphous superconductors is discussed. (20 refs.)

72530 Study of pressure effect on superconductivity in C-15 Laves phase alloys: (Hf, Zr, Ta)V_2 and (Hf, Zr, Nb)V_2 system. Xiong Guang-Cheng, Yin Dao-Le (Dept. of Phys., Peking Univ., Peking, China).
Chin. Phys. (USA), vol.3, no.1, p.29-35 (Jan.-March 1983). [received: May 1983]
The superconducting transition temperatures T_c and its pressure dependence $\partial T_c/\partial P$ on some C-15 Laves phase compounds, $(Zr_{0.5}Hf_{0.5-x}Ta_x)V_2$ $(x\leq0.2)$ and $(Hf_{0.5}Zr_{0.5-x}Nb_x)V_2$ $(x\leq0.2)$ system, have been studied. A description of the experimental apparatus and results is given. Unlike these cases of $(Hf_{1-x}Ta_x)V_2$ and $(Zr_{1-x}Ta_x)V_2$, introduction of Ta in $(Zr_{0.5}Hf_{0.5-x}Ta_x)V_2$ depresses T_c under normal pressure but causes a remarkably higher $\partial T_c/\partial P$. The superconducting transition temperature T_c of $(Zr_{0.5}Hf_{0.45}Ta_{0.05})V_2$ is higher than that of $(Zr_{0.5}Hf_{0.5})V_2$ at high pressure. Based on the band theory method with angular momentum representation, a new relation for the pressure dependence of electron-phonon coupling (i.e. $\partial\ln\eta/\partial\ln V$) is derived. It emphasizes the relative importance of the effect on high angular-momentum components in the conduction band electron wave function of $\partial\ln\eta/\partial\ln V$. This formation is helpful in understanding the above-mentioned experimental results and also gives a reasonable explanation of the fact that T_c of some elements, e.g. Cs, Ba, and La, is substantially enhanced by pressure. (17 refs.)

72531 First-order phase transition boundary between superconducting and SDW phases in the Bechgaard salts. K.Yamaji (Electrotech. Lab., Ibaraki, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1361-72 (April 1983).
Near the SDW-normal phase boundary obtained previously as a function of the transverse transfer energy t' on a quasi 1D Hubbard model, the purely superconducting state is found to extend into the SDW region, once it appears in the normal region. The titled boundary is calculated on the basis of the above-mentioned model with an anisotropic BCS-type interaction. The obtained curve well reproduces the observed *TP* phase diagram, if the author takes $t'\simeq300$ k_B and $dt'/dP\sim0.6$ k_B/kbar. A new RPA expression of the anisotropic plasma frequency for the present model provides the value of t' in remarkable agreement with the above estimate. Examination of the coupled equations for the two kinds of order parameters leads the author to conclude no microscopic coexistence of them. Quasi conductors are argued to be favourable to realise triplet superconductivity.

72532 Phase diagram and critical temperatures of nearly half-filled quasi one-dimensional conductors. Chr.Seidel, V.N.Prigodin (A.F. Ioffe Phys.-Tech. Inst., Acad. of Sci., Leningrad, USSR).
J. Phys. Lett. (France), vol.44, no.10, p.L403-9 (15 May 1983).
Considering a nearly half-filled quasi 1D conductor, variations in bandfilling and in transverse coupling are shown to have similar influence on the critical temperatures of the dielectric (CDW, AF) and superconductor (SS, TS) transitions. Provided $0<g_4<|g_3|$ a metal-to-superconductor transiton occurs at $|\delta\mu|>\delta\mu_c$ where $g_4(\delta\mu_c)=0$, or at $W_\perp>W_c$ where $W_c^2\simeq\varepsilon_F\,T_P$, respectively. Using the theoretical results the author discusses the experimental situation for the new organic conductors $(TMTSF)_2X$. (13 refs.)

72533 UBe_{13}: an unconventional actinide superconductor. H.R.Ott, H.Rudigier (Lab. fur Festkorperphys., Eidgenossische Tech. Hochschule-Honggerberg, Zurich, Switzerland), Z.Fisk, J.L.Smith.
Phys. Rev. Lett. (USA), vol.50, no.20, p.1595-8 (16 May 1983).
Electrical-resistivity, magnetic-susceptibility, and specific-heat data reveal that UBe_{13} is superconducting below 0.85K. Highly anomalous low-temperature electronic properties in both the normal and superconducting states result in an enormous electronic specific-heat coefficient $\gamma=1.1$ J/mole K^2 and a corresponding magnetic susceptibility $\chi=1.5\times10^{-2}$ emu/mole. The superconducting state appears to be extremely stable with an initial slope of the temperature derivative of the critical field $(\partial H_{c2}/\partial T)_{Tc}=-257$ kOe/K. (18 refs.)

72534 Effect of argon on the superconducting transition temperature of lead-argon films. A.I.Eatah (Faculty of Sci., Cairo, Egypt), F.Abd El-Salam, A.Tawfik.
Phys. Status Solidi a (Germany), vol.76, no.2, p.705-8 (16 April 1983).
Lead-argon films of different composition are prepared. The superconductivity is quenched at an argon concentration of 18.5 at.%. A linear dependence of the superconducting transition temperature T_c on the reciprocal of the logarithm of the sample thickness is observed. The reduction in T_c is explained as a result of changes in the electronic band structure. (10 refs.)

72535 Superconductivity of stannous telluride at high pressure. Yu.A.Timofeev, B.V.Vinogradov, E.N.Yakovlev, E.V.Kapitanov, R.O.Kuzyan (Inst. of High-Pressure Phys., Acad. of Sci., USSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1780-1 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3143-4 (Oct. 1982). [received: April 1983]
The authors report on the superconductivity of stannous telluride at high pressure. The electrical resistivity of SnTe as a function of the temperature at high pressure and low temperatures was investigated. The pressure was generated with the aid of anvils made of diamonds of the carbonado type. (8 refs.)

72536 Superconductivity at high pressures in graphite intercalation compounds. L.E.Delong, P.C.Eklund (Dept. of Phys. & Astron., Univ. of Kentucky, Lexington, KY, USA).
Synth. Met. (Switzerland), vol.5, no.3-4, p.291-300 (Feb.-April 1983).
Recent measurements of the pressure dependence of the superconducting transition temperatures of $KHgC_4$, $KHgC_8$, KC_8 and KC_{24} graphite intercalation compounds are summarized and discussed. The role of high pressure as a useful tool in exploring the phase stability, superconductivity, and other physical properties of these materials is emphasized, and possible directions for further research on these compounds are indicated. (37 refs.)

72537 Theory of superconductivity in graphite intercalation compounds. A.Shimizu, H.Kamimura (Dept. of Phys., Univ. of Tokyo, Tokyo, Japan).
Synth. Met. (Switzerland), vol.5, no.3-4, p.301-13 (Feb.-April 1983).
The superconducting transition temperature, T_c, of the first stage alkali-graphite intercalation compounds (GICs), particularly C_8K, has been calculated, assuming that the three-dimensional (3D) alkali-like electrons contribute to superconductivity. The authors suggest that the McMillan formula for T_c is applicable to the GIC systems, in contrast to a previous theoretical treatment by Takada (1982). Thus the mass enhancement factor of the 3D electrons due to the electron-phonon interactions is calculated from first principles. It is confirmed that the interaction with the longitudinal phonon modes in which the carbon and alkali metal atoms vibrate along the *c*-axis is very strong, while that with the phonon modes in which all the atoms vibrate along the layers is screened by the two-dimensional, graphite-like electrons. The former mechanism is characteristic of GICs and this results in superconductivity in GICs. The latter, i.e., the screening effect due to the 2D electrons, is mainly responsible for the reduction of T_c with pressure, recently observed in alkali-amalgam GICs. (12 refs.)

74.20 THEORY

72538 Electroweak effects in p-wave superconductors. D.Bailin (School of Math. & Phys. Sci., Univ. of Sussex, Brighton, England), A.Love.
J. Phys. A (GB), vol.16, no.8, p.L279-84 (1 June 1983).
The unification of electromagnetism and weak interactions leads to anisotropic mixing of the electroweak gauge bosons in p-wave superconductors. It also leads to parity violating components in the gap matrix. (10 refs.)

72539 On inhomogeneous patterns in non-equilibrium superconductor: μ^* model with boundary condition in one dimension. H.Konno (Inst. of Materials Sci., Univ. of Tsukuba, Ibaraki, Japan).
Prog. Theor. Phys. (Japan), vol.69, no.2, p.674-7 (Feb. 1983).
Inhomogeneous patterns of nonequilibrium superconductor are studied by imposing a one dimensional boundary condition upon the modified Rothwarf-Taylor equations combined with the μ^* model. The author found the bifurcation of the spatial modes and the expediency of the 'global-local' concept to understand the spatial patterns. (14 refs.)

72540 Molecular-orbital basis for superconductivity in high- and low-dimensional metals. K.H.Johnson (Dept. of Materials & Engng., MIT, Cambridge, MA, USA), R.P.Messmer.
Synth. Met. (Switzerland), vol.5, no.3-4, p.151-204 (Feb.-April 1983).
A real-space molecular-orbital description of electronic wave functions which are postulated to be the precursors of the superconducting state in high- and low-dimensional metals is presented, based on self-consistent X-alpha scattered-wave (SCF-Xα-SW) molecular-orbital calculations for clusters representing the local molecular environments in these materials. It is shown that there is a persistent correlation between the occurrence of superconductivity in a material and the existence of spatially delocalized molecular orbitals at the Fermi energy which are bonding within and antibonding between 'layers' or 'tubes' of overlapping atomic orbitals that span many atoms, forming a type of 'electron network' at the Fermi energy, as exemplified by pπ 'layered' molecular-orbital topologies in Al and $(TMTSF)_2PF_6$, and by dδ 'tubular' molecular-orbital topologies in Nb and Nb_3Sn. (115 refs.)

72541 Calculation of λ for the quasi-one-dimensional superconductor V_3Si. O.Entin-Wohlman (Dept. of Phys. & Astron., Tel Aviv Univ., Tel Aviv, Israel), M.Weger.
Synth. Met. (Switzerland), vol.5, no.3-4, p.217-28 (Feb.-April 1983).
The band structure and the electron-phonon coupling are calculated for a σ-band hybridized with a δ_1-band using a tight-binding parameters fit for V_3Si. The hybridization gives rise to a sharp peak in the electronic density of states near the Γ_{12} state of the δ_1-band. The variation of the parameter $N(0)I^2$ ($N(0)$—the electronic density of states at the Fermi level I^2—the electron-phonon coupling constant) is studied in the vicinity of the $\Gamma_{12}(\delta_1)$ peak. It is found that there is some compensation between $N(0)$ and I^2; the narrow δ_1-band give rise to a large value of $N(0)$, but a small value of I^2; while the σ-band gives rise to a large value of I^2, but a small value of $N(0)$. As a result, the product $N(0)I^2$ does not follow the behavior of $N(0)$ even qualitatively, and it posseses a maximum far from the peak in $N(0)$. Following this calculation, and previous calculations for the δ_2 and σ-bands, an approximate relationship is developed for the contribution λ_i to λ, coming from the various sub-bands of the 3d band, depending on the individual width of the sub-band, and its contribution to the density of states. (30 refs.)

Theory of superconductivity in graphite intercalation compounds ....See Entry 72537

74.20F BCS theory and its applications

72542 Some considerations on momentum dependence of superconductivity gap. D.Hadziahmetovic (Inst. of Phys., Univ. of Sarajevo, Sarajevo, Yugoslavia), D.Mirjanic.
Fizika (Yugoslavia), vol.15, no.1, p.37-41 (Jan.-March 1983).
It is well known that in solving of superconductivity equation it was assumed that the electron spectrum gap does not depend on momentum in actual momentum region. The authors try to solve this equation without the introduction of this simplifying assumption, and to find the momentum dependence of the superconductivity gap. The Cooper's pair radius will be also calculated. (5 refs.)

74.30 GENERAL PROPERTIES

72543 Influence of some technological factors on the energy losses in superconductors $(Nb_{1-x}Zr_x)_3Sn$ obtained by solid state diffusion. V.Kovachev.
Bulg. J. Phys. (Bulgaria), vol.10, no.1, p.63-74 (1983).
The energy losses of industrial frequencies, magnetic fields up to 1000 A/cm and temperatures 4-15K of superconducting tapes of $(Nb_{1-x}Zr_x)_3Sn (x=0$-$5\%)$ have been studied as a function of the technological parameters during their preparation. Some peculiarities in etching the bronze superconducting matrix and the effect of disrupted substrate screening on the energy losses at the higher temperatures have been considered. The optimum technological conditions for obtaining superconducting tapes of $(Nb_{1-x}Zr_x)_3Sn$ by solid state diffusion have been considered from a viewpoint of the AC properties of these superconductors. (8 refs.)

72544 Specific heat anomaly of $BaPb_{1-x}Bi_xO_3$ at the superconducting transition. M.Sato, H.Fujishita, S.Hoshino (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan).
J. Phys. C (GB), vol.16, no.13, p.L417-21 (10 May 1983).
A specific heat anomaly in $BaPb_{1-x}Bi_xO_3$ single crystals at the superconducting transition has been found by AC calorimetry, in contrast to the previous result of Methfessel et al. (1980) that no specific heat anomaly was observed. The present experimental result seems to support the idea that the superconductivity of the compounds can be described by the simple BCS theory. (18 refs.)

UBe_{13}: an unconventional actinide superconductor .... See Entry 72533

74.30G Response to electromagnetic fields, nuclear magnetic resonance, ultrasonic attenuation

72545 Amplitude dependence of ultrasonic absorption in quenched $Nb_{20}Zr_{80}$. J.L.Wang, G.Weiss, S.Hunklinger (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
J. Phys. Colloq. (France), vol.43, no.C-9, p.533-6 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The ultrasonic attenuation has been measured in a quenched polycrystalline sample of $Nb_{20}Zr_{80}$ at frequencies below 100 MHz (transverse). In the superconducting state, well below the transition temperature of 8.6K, the attenuation contains an intensity dependent component. On cooling down from 1.5K this component first increases but then vanishes below 200 mK. (6 refs.)

72546 Acoustic behaviour of the amorphous superconductor $Cu_{60}Zr_{40}$ at very low temperatures. W.Arnold (Fraunhofer Inst. for Nondestructive Testing, Univ. der Saarbrucken, Saarbrucken, Germany), A.Billmann, P.Doussineau, A.Levelut.
J. Phys. Colloq. (France), vol.43, no.C-9, p.537-9 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
The behaviour of acoustic waves in the amorphous superconductor $Cu_{60}Zr_{40}$ has been studied at temperatures between 70 mK and 2K. Both longitudinal and transverse waves in the 0.5-1 GHz range were used. A discontinuity in the slopes of the absorption as well as of the sound velocity at the transition temperature ($T_c=0.45K$) has been observed. These features are well explained by the tunneling model in which the acoustic behaviour is governed by the coupling of the two-level systems to the electrons in the normal state and to quasiparticles in the superconducting state. (8 refs.)

72547 Anomalous infrared absorption in granular superconductors. G.L.Carr, J.C.Garland, D.B.Tanner (Dept. of Phys., Ohio State Univ., Columbus, OH, USA).
Phys. Rev. Lett. (USA), vol.50, no.20, p.1607-10 (16 May 1983).
Granular superconductors are shown to have a far-infrared absorption that is larger when the samples are superconducting than when they are normal. By contrast, theoretical models for these materials predict that when the samples become superconducting, the absorption should decrease. (13 refs.)

74.40 FLUCTUATIONS AND CRITICAL EFFECTS

72548 Critical-exponent measurements of a two-dimensional superconductor. A.F.Hebard, A.T.Fiory (Bell Labs., Murray Hill, NJ, USA).
Phys. Rev. Lett. (USA), vol.50, no.20, p.1603-6 (16 May 1983).
Voltage-current measurements of an amorphous indium/indium-oxide thin-film composite have yielded values for the exponent $\eta(T)$ describing the power-law decay of the order-parameter correlation function appropriate to the Kosterlitz-Thouless description of phase transitions in two-dimensional systems. A pronounced crossover in the characteristics at the phase-transition temperature is obtained. Theoretical expressions both above and below T_c are verified, and a value of $\eta(T_c)=0.23$ is measured for a film with normal-state sheet resistance of 3560 Ω/□ measured at 8K. (19 refs.)

74.50 PROXIMITY EFFECTS, TUNNELLING PHENOMENA, AND JOSEPHSON EFFECT

72549 Instabilities in superconducting tunnel junctions in differential thermal environments. J.G.Adler, T.A.Will (Dept. of Phys., Univ. of Alberta, Edmonton, Alberta, Canada).
Appl. Phys. Lett. (USA), vol.42, no.10, p.904-5 (15 May 1983).
Instabilities in superconducting tunnel junctions have been studied in three environments: low pressure He gas, normal liquid He I, and superfluid He II. It is demonstrated that the effect arises at a bias voltage V_0 where junction dissipation is sufficient to drive a region of the electrode(s) normal. The transition is accompanied by a small excess current, which is due to the appearance of electrode resistance and junction heating. For Pb electrode junctions immersed in liquid He the critical junction dissipation marks the outset of film boiling, which shows up as excessive noise in the tunneling curves. This critical heat flux, $\simeq 1$ W/cm² at 4.2K, limits the useful energy range for tunneling spectroscopy and leads to catastrophic burnout of high density Josephson arrays. (16 refs.)

72550 Imaging of spatial structures in superconducting tunnel junctions by electron-beam scanning. H.Seifert, R.P.Huebener (Phys. Inst. II, Univ. Tubingen, Tubingen, Germany), P.W.Epperlein.
Phys. Lett. A (Netherlands), vol.95A, no.6, p.326-30 (9 May 1983).
The voltage change caused in a current-biased superconducting tunnel junction by scanning the junction surface with an electron beam can serve to generate a two-dimensional image of spatial structures within the specimen. Depending upon the bias point during the scanning process, an image of local variations in the tunneling current density due to variations of the tunnel barrier resistance or in the energy gaps of the electrodes is obtained. PbAuIn/PbBi cross-line and SiO-window junctions have been used to demonstrate this imaging technique. (6 refs.)

72551 On the microscopic theory of the proximity effect in normal metal-superconductor sandwiches. A.D.Zaikin, G.F.Zharkov (Dept. of Theoretical Phys., Lebedev Inst., Moscow, USSR).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.331-4 (9 May 1983).
A theory of the proximity effect in clean normal metal-superconductor sandwiches at low temperatures $T \ll T_c$ is developed. It is shown that the value of the superconducting order parameter near the NS-interface is equal to nearly half of its value Δ_0 far from the NS-interface. The distance at which $\Delta(x)$ changes to Δ_0 is of the order of ξ_0. (9 refs.)

72552 Transient response of superconducting indium microbridges to supercritical current pulses. D.J.Frank, M.Tinkham (Phys. Dept., Harvard Univ., Cambridge, MA, USA), A.Davidson, S.M.Faris.
Phys. Rev. Lett. (USA), vol.50, no.20, p.1611-14 (16 May 1983).
Superconducting sampling circuits have been used to investigate the transient response of long indium microbridges to current pulses in excess of their critical currents. For the first time, the rising-edge kinetic inductance spike and the nonzero minimum voltage have been observed, as well as the delay time until the normal state appears. These results are in reasonable agreement with a detailed theoretical model of the experiment and yield an estimate of 140 ps for τ_E, the inelastic scattering time, in indium. (18 refs.)

72553 Flux quantization in a superconducting closed loop with more than two Josephson junctions. W.Richter, F.Dettmann (Sektion Phys., Friedrich-Schiller-Univ. Jena, Jena, Germany).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K95-8 (1 April 1983).
The critical current versus magnetic flux characteristic of a DC SQUID with two Josephson junctions is periodic in the magnetic flux with a periodicity of one flux quantum Φ_0. The authors have investigated theoretically the flux quantization of a superconducting closed loop composed of 2n series Josephson junctions and an inductance. (3 refs.)

72554 Superconducting properties of metallic heterostructures. I.K.Schuller (Argonne Nat. Lab., Argonne, IL, USA), C.M.Falco.
Synth. Met. (Switzerland), vol.5, no.3-4, p.205-16 (Feb.-April 1983).
Reviews recent results on the superconducting properties of artificially prepared metallic heterostructures. The sputtering system used to prepare these materials is described in detail along with a calculation of the thermalization of sputtered atoms. The structure of Nb/Cu and Nb/Ti heterostructures is discussed, as are T_c, energy gap, and phonon frequency measurements. (29 refs.)

74.55 TYPE-I SUPERCONDUCTIVITY

72555 Fluctuation-enhanced electrical conductivity of thin superconducting films of tin. S.B.Kalra, P.N.Dheer (Dept. of Phys. & Astrophys., Univ. of Delhi, Delhi, India).
Indian J. Cryog., vol.7, no.4, p.177-83 (1982).
Measurements of the excess electrical conductivity of thin superconducting films of tin (thickness much less than the temperature dependent coherence length) due to thermodynamic fluctuations of the order parameter above the transition temperature, T_c have been carried out on films deposited on (a) glass substrates held at ~300K, (b) glass substrates held at ~77K and (c) glass substrates precoted with a layer of LiF and held at ~300K. The study has been carried out at low as well as moderately high electric fields. (28 refs.)

74.60 TYPE-II SUPERCONDUCTIVITY

74.60E Mixed state, H_{c2}, surface sheath

72556 Magnetic properties in the mixed state of ferromagnetic superconductors. O.Sakai (Dept. of Phys., Tohoku Univ., Sendai, Japan), M.Suzuki, S.Maekawa, M.Tachiki, G.W.Crabtree, F.Behroozi.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1341-51 (April 1983).
The lower and the upper critical fields H_{c1} and H_{c2}, and the slope of magnetisation at H_{c2}, $(\partial M/\partial H)_{c2}$, are calculated in ferromagnetic superconductors. The theory takes account of the electromagnetic and the s-f exchange interactions between conduction electrons and localised f-electrons. When temperature decreases, $(\partial M/\partial H)_{c2}$ in the mixed state increases and diverges at a certain temperature. This indicates that below this temperature, the transition at H_{c2} is of a first order. Near the spin ordering temperature, H_{c2} decreases more rapidly than H_{c1} with decreasing temperature. The theoretical results are compared with experimental results in single crystals $ErRh_4B_4$ in detail. (40 refs.)

72557 Upper critical field in two-dimensional superconductors. S.Maekawa (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1352-60 (April 1983).
The upper critical field in two-dimensional superconductors is calculated by taking into account quantum corrections due to the Anderson localisation to the theory of dirty superconductors in the order of $(\epsilon_F\tau_0)^{-1}$ where ϵ_F and τ_0 are the Fermi energy and the relaxation time of an electron, respectively. The upper critical field is enhanced at low temperatures. This is because the diffusion constant of electrons is depressed and the Coulomb repulsive interaction modified by the localisation becomes small in the magnetic field. Discussion is given on the upward curvature of upper critical field of layered superconductors in the field perpendicular to the layers.

72558 Effect of alloying and intercalation of superconductivity of transition metal dichalcogenides. M.Ikebe, Y.Muto (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan).
Synth. Met. (Switzerland), vol.5, no.3-4, p.229-44 (Feb.-April 1983).
The superconducting transition temperature T_c and the anisotropy ratio of the upper critical field parallel and perpendicular to the layer plane have been measured on 2H- and 4Ha-$Nb_{1-x}Ta_xSe_2$ mixed crystals and on 2H-$Ta_{1-x}Nb_xS_2$ with and without pyridine intercalation. 4Hb-$Ta_{0.95}Nb_{0.05}S_2$ and 4Hb-$Ta_{0.95}Nb_{0.05}S_2(Py)_{1/2}$ which have a mixed coordination structure have also been studied. The results have been analyzed on the basis of the KLB theory of quasi-two-dimensional superconductivity. The analyses show that the mixed crystal system remains in strongly anisotropic three-dimensional superconductivity. On the other hand, the anomalously large anisotropy of the H_{c2} of intercalation compounds can only be explained by the use of the KLB theory, indicating attainment of quasi-two-dimensional superconductivity. In the 4Hb crystal, the layers are more strongly decoupled, and the existence of semimetallic octahedral layers has been found to be important in determining the interlayer superconductive coupling. (23 refs.)

72559 Superconductivity of alkali metal intercalated $ZrSe_2$. Y.Onuki (Saitama Inst. of Technol., Saitama-ken, Japan), S.Yamanaka, R.Inada, M.Kido, S.Tanuma.
Synth. Met. (Switzerland), vol.5, no.3-4, p.245-55 (Feb.-April 1983).
Alkali metal intercalated $ZrSe_2(A_xZrSe_2)$ has been synthesized by the reaction of $ZrSe_2$ single crystals with n-butylithium in hexane solution, or alkali metals (Na, K, Rb, Cs) in hexamethylphosphoric triamide solution. Semiconducting $ZrSe_2$ has been converted into a metallic substance by the alkali metal intercalation. Superconductivity has been found for Li_x-, Na_x-, K_x-, Rb_x- and Cs_xZrSe_2 $(0<x\leq 1)$ below 1.7, 2.0, 2.1, 1.7, and 1.4, respectively. The angular dependence of the upper critical fields H_{c2} for A_xZrSe_2 is interpreted by the effective mass model. The Ginzburg-Landau coherence lengths perpendicular to the layer planes of the crystals at zero temperature are ten to twenty times larger than the layer repeat distances, showing a three-dimensional character. Anisotropic superconductivity is discussed on the basis of the Fermi surface of A_xZrSe_2 whose electron number is determined by the charge transfer from alkali metal atoms to $ZrSe_2$. (16 refs.)

72560 Superconductivity of graphite intercalation compounds—stage and pressure dependence of anisotropy. Y.Iye, S.Tanuma (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan).
Synth. Met. (Switzerland), vol.5, no.3-4, p.257-76 (Feb.-April 1983).
Superconductivity of graphite intercalation compounds with KHg, RbHg and $KTl_{1.5}$ was studied with a particular emphasis on the two-dimensional anisotropy. The stage and pressure dependence of the critical field clearly manifests the way to two-dimensionality is controlled by changing the layer separations. It is argued that the major part in the superconductivity of this class of materials is played by electrons in the intercalant band rather than those in the graphitic band. (10 refs.)

72561 Superconducting mercury and thallium intercalation compounds. L.A.Pendrys, R.A.Wachnik, F.L.Vogel (Lab. for Res. On The Structure of Matter, Univ. of Pennsylvania, Philadelphia, PA, USA), P.Lagrange.
Synth. Met. (Switzerland), vol.5, no.3-4, p.277-90 (Feb.-April 1983).
Superconducting properties of the graphite intercalation compounds, $KHgC_8$, $RbHgC_8$, $KTl_{1.5}C_4$ and $KTl_{1.5}C_8$, having T_c values of 1.9, 1.44, 2.7 and 2.45K, respectively, have been studied using an AC magnetic susceptibility technique. The second critical field, H_{c2}, of $KTl_{1.5}C_4$ was extrapolated from measurements to ≈20 kOe at zero temperature for the DC magnetic field applied perpendicular to the $\vec{c}$-axis. A nearly temperature independent anisotropy of ≈5 was observed. The compound $KHgC_8$ has an extrapolated anisotropy in H_{c2} of ≈25 at T_c which appears to increase strongly at reduced temperatures. However, the extrapolated value at $T=0$ is ≈3 kOe for the magnetic field perpendicular to the $\vec{c}$-axis. The values at T_c and H_{c2} determined for $KTl_{1.5}C_4$ are the highest observed to date in a graphite intercalation compound. In spite of large values of H_{c2} and of anisotropy in H_{c2}, no clear evidence of quasi 2D behavior is evident at any temperature and anisotropic 3D models should describe superconducting behavior in these compounds. (30 refs.)

74.60G Flux pinning; fluxon-defect interactions

72562 Pinning in NbN films. Ding Shiying (Dept. of Phys., Nanjing Univ., Nanjing, China).
Chin. Phys. (USA), vol.3, no.1, p.169-72 (Jan.-March 1983). [received: May 1983]
An analysis is made of experimental data of NbN thin films prepared by reactive sputtering. Results show that the magnetic field variation of the pinning force density F_p could be fitted to the Kramer relation,

$F_p \sim b^{1/2}(1-b)^2$, where b is the normalized induction. A study has been made of the flux pinning mechanisms in films. The authors have also compared the $J_c(H)$ of NbN with those of other high field superconductors, foreseeing the possibility of technical applications of B1 compounds. (5 refs.)

72563 Computer simulation of flux pinning in type-II superconductors. E.H.Brandt (Inst. fur Phys., Max-Planck-Inst. fur Metallforschung, Stuttgart, Germany).
Phys. Rev. Lett. (USA), vol.50, no.20, p.1599-602 (16 May 1983).
Random point pinning of ideal or defective flux-line lattices is simulated on a computer. For weak pins, Larkin and Ovchinnkov's (1979) two-dimensional collective pinning is confirmed: $j_c = \text{const} \times n_p \langle f_p^2 \rangle / R_p c_{66}$ (j_c is the critical current; n_p, f_p, and R_p are the density, force, and range of pins; and c_{66} is the shear modulus). The constant is determined. Defective lattices are pinned more strongly by factors 1.3 to 3, explaining the observed history effect. A pronounced jump in the curves $j_c(f_p)$ indicates the onset of plastic deformation. (17 refs.)

72564 Thermally induced resistive domains in thin superconducting indium films. Yu.M.Ivanchenko, P.N.Mikheenko (Physicotech. Inst., Acad. of Sci., Donetsk, Ukrainian SSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.380-8 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.684-98 (Aug. 1982). [received: May 1983]
A phenomenological theory describing localized resistive regions in superconducting thin films is used to introduce the concept of elementary resistive domains which are analogs of phase slip centers characteristic of superconducting thin channels and microbridges. The main feature of elementary resistive domains is the same as that of phase slip centers: energy dissipation in the domains occurs in a region of width $2l_E$, where l_E is the depth of penetration of a longtitudinal electric field into the superconductor. It is shown that the number of jumps in the current-voltage characteristic of a film with a domain, recorded under constant-current conditions, is a function of the parameters of the film and is independent of the thermostat temperature. An estimate of l_E is obtained using the experimental current-voltage characteristics of elementary domains and allowing for the inhomogeneous distribution of the current across the film width. Experiments are reported in which resistive domains (including elementary ones) are induced by heaters in the form of evaporated copper films. Characteristic features of domains formed in the presence of a heater include a wide range of currents in which such domains exist, and their disappearance on switching off the heater if the value of the transport current does not exceed a certain critical value, the threshold nature of the excitation at low rates of heat flow, etc. The mechanism of formation of these superdomains is explained schematically and experiments are considered for the separate determination of the currents responsible for the appearance of domains. (17 refs.)

74.60J Critical currents

72565 Influence of a current and of a magnetic field on the properties of magnetic superconductors of the HoMo$_6$S$_8$ type. A.I.Buzdin, L.N.Bulaevskii, S.V.Panyukov (P.N. Lebedev Phys. Inst., Acad. of Sci., USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.430-40 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.768-86 (Aug. 1982). [received: May 1983]
The authors investigate the properties of the inhomogeneous domain-type magnetic structure (DS phase) produced in magnetic superconductors such as $HoMo_6S_8$ in the region where superconductivity and magnetism coexist. They show that the superconducting critical current in the *DS* phase decreases to zero when the temperature is lowered to $T_{c2}^{(c)}$ (the supercooling temperature of the *DS* phase). The wave vector of the magnetic structure decreases at the same time with increasing current flowing through the sample. They investigate the behavior of the *DS* in a magnetic field, obtain the phase diagram in the (H,T) plane. In the region where the field penetrates, the *DS* phase is substantially altered: new peaks $2nQ$ (n is an integer) appear in the neutron scattering, and the wave vector Q decreases with increasing field. 74.90 OTHER TOPICS IN SUPERCONDUCTIVITY

72566 High magnetoresistivity of a system of weakly coupled superconducting chains. K.B.Efetov (Lab. de Phys. des Solides, Univ. de Paris-Sud, Orsay, France).
J. Phys. Lett. (France), vol.44, no.10, p.L369-74 (15 May 1983).
The resistivity of a system of weakly coupled superconducting chains with breaks is calculated. It is shown that an external magnetic field can influence considerably this resistivity. (7 refs.)

72567 Remarks on the experiment of winding number dependence of the Aharonov-Bohm effect. A.Inomata (Dept. of Phys., State Univ. of New York, Albany, NY, USA).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.176-8 (25 April 1983).
A theoretical basis is provided for the recent experimental demonstration of the winding number dependence of the Aharonov-Bohm effect by Deaver and Donaldson (see ibid., vol.89, p.178, 1982). An N-turn superconducting ring around flux is shown to have quantized flux states with $\Delta\Phi = \Phi_0/N = hc/(2Ne)$. (9 refs.)

72568 Ground-state entropy of the *q*-state Potts antiferromagnet in a magnetic field. D.S.Hajdukovic, S.Milosevic (Dept. of Phys. & Meteorology, Faculty of Natural & Math. Sci., Belgrade, Yugoslavia).
Phys. Lett. A (Netherlands), vol.95A, no.5, p.249-51 (2 May 1983).
Presents a simple method to obtain reliable ground-state entropies of the q-state Potts antiferromagnet in an external magnetic field. As an example, the ground-state entropy for the triangular lattice is established for all q. In the particular case $q=2$, the authors method gives results which coincide with the first-order approximation obtained by the corner transfer matrix method. (6 refs.)

75.10H Ising and other classical spin models

72569 Time-dependent correlation functions of the transverse Ising chain at the critical magnetic field. B.M.McCoy, J.H.H.Perk, R.E.Shrock (Inst. for Theoretical Phys., State Univ. of New York, Stony Brook, NY, USA).
Nucl. Phys. B, Field Theory & Stat. Syst. (Netherlands), vol.B220 (FS8), no.1, p.35-47 (16 May 1983).
The authors study the correlation function $\langle\sigma_0^x(t)\sigma_n^x(0)\rangle$ of the transverse Ising model in a critical field whose Hamiltonian is ${}^1/_2\Sigma_l\{\sigma_l^x\sigma_{l+1}^x - \sigma_l^z\}$. At an arbitrary temperature T they relate the autocorrelation to a Fredholm determinant. Moreover at $T=0$ the correlations are given by a Painleve V function for all n. The long-time asymptotic behavior of this function is found and the connection problem is studied. This result contains oscillatory terms which are related to the density of states at the Brillouin zone boundary. (14 refs.)

72570 Critical amplitudes for the random Ising system. S.A.Newlove (Phys. Dept., Univ. of Edinburgh, Edinburgh, Scotland).
J. Phys. C (GB), vol.16, no.13, p.L423-6 (10 May 1983).
The critical amplitude ratios C_+/C_-, A_+/A_- and f_+/f_- are calculated to one loop and compared with their experimental values. (8 refs.)

72571 The antiferromagnetic phase of the Ising model with first- and second-neighbour interactions. J.Doczi-Reger, P.C.Hemmer (Inst. of Theoretical Phys., Univ. of Trondheim, Trondheim, Norway).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K67-71 (1 April 1983).
Two-dimensional Ising systems with nearest-neighbour (nn) and next-nearest-neighbour (nnn) interactions can model interesting physical systems as adsorbed atoms on crystal surfaces, or layered crystals. The authors obtain analytic results for the phase boundary for the antiferromagnetic phase. They use the interface method to determine this second-order transition line. Although the interface method is approximate it has in several instances been shown that it yields qualitatively correct and even qualitatively good results. (7 refs.)

75.10J Heisenberg and other quantized localized spin models

72572 Analysis of the Bethe ansatz equations of the XXZ model. O.Babelon, H.J.de Vega, C.M.Viallet (Lab. de Phys. Theorique et Hautes Energies, Paris, France).
Nucl. Phys. B, Field Theory & Stat. Syst. (Netherlands), vol.B220 (FS8), no.1, p.13-34 (16 May 1983).
The authors analyse the Bethe ansatz equations of the *XXZ* model in the antiferromagnetic region, without assuming a priori the existence of strings. Excited states are described by a finite number of parameters. These parameters satisfy a closed system of equations, which they obtain by eliminating the parameters of the vacuum from the original Bethe ansatz equations. Strings are only particular solutions of these equations. (9 refs.)

72573 On the gauge equivalence of the Landau-Lifshitz and the nonlinear Schrodinger equations on symmetric spaces. V.G.Makhankov, O.K.Pashaev (Joint Inst. for Nuclear Res., Dubna, USSR).
Phys. Lett. A (Netherlands), vol.95A, no.2, p.95-100 (18 April 1983).
The gauge equivalence between a generalized Heisenberg spin chain (G/H) in the classical and continuum limit and the nonlinear Schrodinger equation (NLSE), with special attention to noncompact groups, is established. It has been demonstrated that noncompact groups allow a richer spectrum of possible reductions of the Heisenberg system to the NLSE. Some specialities of the model with nontrivial boundary conditions are discussed. The gauge equivalence between single-axis anisotropic Landau-Lifshitz equations (LLE) and isotropic LLE is briefly discussed. (13 refs.)

72574 Boost operator and its application to quantum Gelfand-Levitan equation for Heisenberg-Ising chain with spin one-half. K.Sogo, M.Wadati (Inst. of Phys., Univ. of Tokyo, Tokyo, Japan).
Prog. Theor. Phys. (Japan), vol.69, no.2, p.431-50 (Feb. 1983).
The quantum inverse scattering problem for the Ising-like *XXZ* model is studied. It is found that the boost operator plays an essential role in the analysis. In terms of the boost operator, the bound state operators are defined and the quantum Gelfand-Levitan equation is derived in a natural way. The quantum inverse scattering problem for the *XY*-like *XXZ* model is also discussed. In addition, the boost operators for Calogero (1975) systems and Toda lattice are explicitly given. (24 refs.)

72575 Magnetic susceptibility of neutron and electron irradiated quartz versus the 'glassy' thermal conductivity. C.Laermans (Phys. Dept., Katholieke Univ., Leuven, Leuven, Belgium), A.Van den Bosch, J.Cornelis, J.Vansummeren.
J. Phys. Colloq. (France), vol.43, no.C-9, p.513-16 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
Static magnetic susceptibility measurements have been carried out on crystalline quartz samples after fast neutron irradiation and high energy electron irradiation, both for two doses. The samples were these used for former thermal conductivity measurements or had been joined, during irradiation, to the samples in which dynamic experiments have been done before so that their 'glassy' behavior is known. While the thermal conductivity shows a comparable decrease for the two kinds of irradiation at temperatures below 1K, the behavior of the static paramagnetic susceptibility is different for both kinds of irradiation. Consequently, the tunneling states and the paramagnetic centers are not directly related. (13 refs.)

72576 On the magnetic behaviour of some hydrogen bonded molecules in crystals. M.M.Abdel-Kader (Phys. Dept., Univ. of Cairo, Giza, Egypt).
Mol. Phys. (GB), vol.48, no.6, p.1145-54 (20 April 1983).
The effect of the hydrogen bonding on the magnetic anisotropy of *o*-halogenobenzoic acids and some derivatives of phenol, namely 2-aminophenol, 2,3-dimethylphenol and 2-methyl-3-bromophenol, is studied. These molecules are of known crystal structures. The crystal susceptibilities (χ_1, χ_2 and χ_3) of each compound were measured. From these measurements and the molecular orientation, the principal molecular susceptibilities (K_1, K_2 and K_3) have been calculated. The observed magnetic data are interpreted in the light of the structures of these molecules and their hydrogen bonding systems. (42 refs.)

72577 Magnetic interactions in solid oxygen. R.J.Meier (Natuurkundig Lab., Univ. van Amsterdam, Amsterdam, Netherlands).
Phys. Lett. A (Netherlands), vol.95A, no.2, p.115-17 (18 April 1983).
A semi-empirical model is applied to describe the magnetic properties of solid oxygen. The behaviour of the susceptibility is explained and a magnetic three-sublattice structure for β-oxygen is found to be favoured over a two-sublattice structure. (7 refs.)

72578 The magnetic properties of 3*d* impurities: Fe and Mn in Nb_3Ga A15 type matrix. J.Sosnowski (Electrotech. Inst., Warsaw, Poland), T.Mydlarz.
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.455-60 (April 1983).
The results of the investigations of magnetic properties of Fe and Mn impurities in Nb_3Ga A15 type matrix are presented. The values of the Curie-Weiss parameters for arc-melted $Nb_{78}Ga_{22-x}Fe_x$, $Nb_{80}Ga_{20-x}Mn_x$ and annealed $Mb_{78}Ga_{22-x}Mn_x$ samples are given. Observed dependences are interpreted according to the model of the influence of nearest environment of given impurity atom on its magnetic properties. On the basis of this suggestion other magnetic parameters of impurities such as: number of magnetic atoms, mean exchange field, pair breaking have been estimated. (11 refs.)

72579 Spin polarization and relaxation in magnetically doped semiconductors. Yu.G.Semenov (Inst. of Electrical Semiconductors, Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.31-3 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.449-51 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
A description is given of exchange scattering of photocarriers by localized magnetic moment in which the effective exchange field produced by the latter, which leads to giant spin splitting of energy bands in magnetically doped semiconductors, is taken into account. An expression is given for the corresponding probability of relaxation spin transitions. (4 refs.)

72580 Special solution of the mode-coupling equations for a two-component magnetic system. W.Schattke (Inst. fur Theoretische Phys., Univ. Kiel, Kiel, Germany).
J. Stat. Phys. (USA), vol.30, no.3, p.607-15 (March 1983).
The validity of the vertex approximation for the nonlinear Langevin equations has been investigated in the special case of a two-component magnetic system without spatial correlation. The exact solution of the equation resulting from the vertex approximation is compared with that of the original equation. Agreement is found in the regime of small nonlinearity. In the opposite regime, especially near a critical slowing down, both solutions differ significantly. (6 refs.)

75.25 SPIN ARRANGEMENTS IN MAGNETICALLY ORDERED MATERIALS (NEUTRON STUDIES, ETC)

72581 A possibility of triple-Q incommensurate magnetic structure in $RbFeCl_3$-type triangular antiferromagnets. H.Shiba (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan), N.Suzuki.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1382-6 (April 1983).
A theoretical examination is made on whether the triple-Q incommensurate magnetic structure can be realised in $RbFeCl_3$-type magnets. A comparison of free energies among the single-Q, double-Q and triple-Q states shows that there is a good chance to have the triple-Q phase in this system. An argument based on the ϵ expansion is also presented in this connection.

72582 Magnetic properties of $Cr_{1/3}NbS_2$. T.Miyadai, K.Kikuchi (Dept. of Phys., Hokkaido Univ., Sapporo, Japan), H.Kondo, S.Sakka, M.Arai, Y.Ishikawa.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1394-401 (April 1983).
An intercalated 2H-type layer compound, $Cr_{1/3}NbS_2$, was investigated by magnetic and neutron diffraction measurements. It was found that this compound is a helimagnet with a very long period along the *c*-axis and with the spins in the *c*-plane. The magnetic behaviour is similar to that of an easy-plane type ferromagnet except for the magnetisation curve in the *c*-plane. The Curie temperature is 127K. The saturation magnetisation corresponds to 2.9 μ_B/Cr. The uniaxial anisotropy constant, K_1, is -1.46×10^6 ergs/cc at 4.2K. The magnetisation curve in the *c*-plane shows a metamagnetic behaviour, the critical field of which is as low as 1.5 kOe except near T_c. Small angle scattering measurements showed a helical structure with $Q=0.013$ Å^{-1} (480

Å period). The helical spin structure and the metamagnetism is explained as due to the antisymmetric exchange interaction. (12 refs.)

72583 On the magnetic structure of a hexagonal Ising antiferromagnetic. F.Matsubara (Dept. of Engng. Sci., Tohoku Univ., Sendai, Japan).
Solid State Commun. (USA), vol.46, no.4, p.329-32 (April 1983).
Domain wall free energies are calculated in a hexagonal Ising antiferromagnet and shown to be very small compared with those in an ordinary two-sublattice antiferromagnet. It is suggested that the magnetic structure of its higher temperature ordered phase is one in which many domains are tangled with each other. Some comments are given on experimental results in $CsCoCl_3$ and $CsCoBr_3$. (10 refs.)

72584 Surface magnetic structure analysis of Ni(001) by polarized electron diffraction. R.Feder (Theoretische Festkorperphys., Univ. Duisburg, Duisburg, Germany), S.F.Alvarado, E.Tamura, E.Kisker.
Surf. Sci. (Netherlands), vol.127, no.1, p.83-107 (April 1983).
For spin-polarized low-energy electrons diffracted from ferromagnetic Ni(001), the exchange- and the spin-orbit-induced scattering asymmetries A_{ex} and A_{so} of two diffracted beams have been simultaneously measured at $T=300K$ and at $T=520K$ for several constant energies as functions of the polar angle of incidence. Corresponding 'rocking curves' calculated by dynamical theory are in generally good agreement with the data. Analysis of A_{so} shows firstly that an energy-dependent exchange approximation is adequate, secondly that the topmost interlayer spacing is essentially bulk-like with a possible slight outward relaxation (1%), and thirdly that 3p→3d excitation is significant. From A_{ex} the following magnetic information is obtained: The surface magnetization for $T=300K$ and 520K is such as to imply, via extrapolation by mean field theory, a $T=0$ value slightly enhanced (by $+5\%\pm5\%$) with respect to the bulk magnetization. The spin asymmetries of localized and uniform inelastic processes are very small, leading, for incident electron energy 69 and 89 eV, to a combined inverse mean free path asymmetry of less than 0.3%. (47 refs.)

75.30 MAGNETICALLY ORDERED MATERIALS, OTHER INTRINSIC PROPERTIES

(for critical point effects, see 75.40)

75.30C Saturation moments and magnetic susceptibility

72585 Magnetic history of hexanediammonium tetrachloroferrate(II). M.A.Semary, M.M.Abdel-Kader, M.F.Mostafa (Phys. Dept., Faculty of Sci., Univ. of Cairo, Giza, Egypt).
Chem. Phys. Lett. (Netherlands), vol.96, no.6, p.641-4 (29 April 1983).
The magnetic susceptibility of the two-dimensional antiferromagnet $(CH_2)_6(NH_3)_2\ FeCl_4$ is reported. The compound has unusual dependence on its magnetic history below its Neel temperature T_N. Though the magnetic ordering is associated with a structural distortion, this distortion does not seem to explain the magnetic behaviour of the compound. The results have been interpreted in terms of mixed magnetic phases which are likely to exist when the sample is cooled in a magnetic field. (11 refs.)

72586 Magnetic properties of bulk amorphous alloy Dy_4Co_3. A.Apostolov (Faculty of Phys., Sofia Univ., Sofia, Bulgaria), H.Hristov, T.Midlag, M.Mikhov, V.Skumriev.
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.159-64 (April 1983).
The magnetic susceptibility was investigated by the transition balance method in the 77-400K temperature range, and the magnetization was studied in the temperature range 4.2-300K using a vibrating sample magnetometer in magnetic fields up to 60 kOe, and by a ballistic magnetometer in magnetic fields up to 140 kOe. The temperature dependence of saturation magnetization (σ_s), remanent magnetization (σ_r), coercivity (H_c) and anisotropy (W) were obtained from the hysteresis loops and the initial magnetization curves. The temperature changes of σ_s and σ_r were qualitatively similar, showing well defined maxima at 40K and minima at 20K. The transition temperature from the paramagnetic to magnetic ordered state—$T_c=(69.5\pm0.5)K$—was determined from the magnetization curves by the Belov-Goryaga thermodynamic method. (10 refs.)

72587 Magnetic ordering of the intermetallic compound Gd_2Au. H.Gamari-Seale, V.Bredimas (Nuclear Res. Centre, Demokritos, Attikis, Greece).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.131-5 (April 1983).
Magnetization measurements on polycrystalline Gd_2Au indicate that the magnetic ordering of the compound is extremely sensitive to the sample preparation, thus explaining the contradictory results reported in the literature. (6 refs.)

72588 Magnetic properties of the R_5Sb_3 compounds (R=La, Pr, Nd, Gd, Tb, Dy, Ho, Er, Tm and Y). J.K.Yakinthos, I.P.Semitelou (School of Engng., Democritos Univ. of Thrace, Xanthi, Greece).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.136-40 (April 1983).
Susceptibility measurements were performed on the rare earth antimonides with the composition R_5Sb_3 in the temperature range 4.2 to 300K under a constant magnetic field of 1 kOe. All the compounds, except La_5Sb_3 and Y_5Sb_3, show an antiferromagnetic behaviour with Neel temperatures between 12 K(Tm) and 109 K(Gd). La_5Sb_3 and Y_5Sb_3 show a temperature independent susceptibility. (6 refs.)

75.30D Spin waves

(see also 76.50 Spin wave resonance)

72589 Surface magnetostatic waves at an interface between two magnetic materials. I.A.Gilinskii (Inst. of Semiconductor Phys., Siberian Branch, Acad. of Sci., Novosibirsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.455-8 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A theoretical study is used to show that the low-frequency branch of such waves represents true surface oscillations, i.e. it does not dissociate as a result of emission of bulk magnons into the interiors of the two crystals. (11 refs.) *A.T.*

72590 Spectrum and damping of spin waves in size-quantized ferromagnetic semiconductor films. M.Sh.Erukhimov (L.V. Kirenski Inst. of Phys., Acad. of Sci., Krasnoyarsk, USSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1751-4 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3096-101 (Oct. 1982). [received: April 1983]
A study is made of the spin wave spectrum in size-quantized ferromagnetic films with an *s-d* exchange interaction. The regions of collisionless Landau damping are determined. The behavior of the dispersion laws of the lower and upper spin wave branches at the boundaries of such regions is investigated. New quantum spin waves are obtained in triangular transparency windows. It is shown that the damping of the lower and upper spin wave branches exhibits strong oscillations when the magnon wave vector and the thickness of the film are varied. The oscillation period and the temperature dependence of the oscillation amplitude are determined. (11 refs.)

72591 Boundaries of the long-wavelength part of the spin wave spectrum. A.V.Lavrinenko, G.A.Melkov, N.A.Davidenko (T.G. Shevchenko State Univ., Kiev, Ukrainian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1776-7 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3136-7 (Oct. 1982). [received: April 1983]
The upper and lower boundaries of spin wave spectra in yttrium iron garnet (YIG) single crystals were detected experimentally at room temperatures for wave vectors k→0. The experiments were carried out on spherical samples of diameter 1.5-3 mm magnetized in the direction of the [111] easy axis with FMR line widths of 0.3-0.5 Oe. The position of the upper boundary of the spin wave spectrum was determined from the minimum of the threshold of the longitudinal spin wave pumping. The frequency corresponding to the lower boundary of the spectrum was determined by exciting dynamic instability in ferrites, which gave rise to spin waves at the bottom of the spectrum. The frequency of such waves can be determined from their electromagnetic radiation. (6 refs.)

72592 Relaxation in ferromagnetic metals. S.O.Gladkov (INst. of Chem. Phys., Acad. of Sci., USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.452-5 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.806-12 (Aug. 1982). [received: May 1983]
The interaction between nuclear spin waves and conduction electrons is considered. It is shown that these processes are very important at infralow temperatures. They lead to large scattering probabilities and determine the establishment of the thermodynamic equilibrium in the subsystems. A theory of relaxation in ferromagnetic metals at intraflow temperatures is developed. (11 refs.)

72593 Kinetic theory of parametric excitation of spin waves in the case of parallel pumping. V.P.Seminozhenko, V.L.Sobolev, A.A.Yatsenko (Donets Physicotech. Inst., Acad. of Sci., Ukrainian SSR).
Theor. & Math. Phys. (USA), vol.52, no.3, p.907-13 (Sept. 1982). Translation of: *Teor. & Mat. Fiz. (USSR)*, vol.52, no.3, p.443-52 (Sept. 1982). [received: May 1983]
Kinetic equations are constructed for normal and anomalous mean values of the type $f_p=\langle a_p{}^+ a_p\rangle$, $\sigma_p=\langle a_p a_{-p}\rangle$ ($a_p{}^+$, a_p are magnon operators) for ferromagnets under conditions of parallel pumping. Expressions are obtained for the generalized collision integrals in the equations for the functions f_p and σ_p. Methods of obtaining solutions of the kinetic equations in a steady regime are discussed. An equation is formulated that describes the nonequilibrium states of the magnons in a region of the spectrum far from resonance. (14 refs.)

72594 Excitation and propagation of dimensionless magnetostatic types of waves and oscillations in rectangular yttrium-iron-garnet rods. B.E.Zhurilenko.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.585-91 (April 1983). In Russian.
The spectrum of magnetostatic body waves (MSBW) and volume oscillations (MSVO) has been investigated in a rectangular yttrium-iron-garnet rod under excitation by different antenna systems. It is shown theoretically and experimentally that, besides modes with the wave number depending on sample dimensions, it is possible to excite MSBW and MSVO modes differing only in the wave field structure. For these 'dimensionless' modes dispersion dependences and expressions are obtained which describe the wave field structure both inside and outside the sample. (9 refs.)

75.30E Exchange and superexchange interactions

(see also 71.70 Level splitting and interactions)

72595 Widths of magnetic exciton lines exhibited by cubic Laves phases $PrAl_2$ and $PrNi_2$. V.L.Aksenov, E.A.Goremychkin, T.Frauenheim (Joint Inst. for Nuclear Res., Dubna, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.496-502 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Experimental data on the inelastic scattering of neutrons were used to consider the temperature dependence of the line width of localized magnetic excitations in rare-earth intermetallics $PrAl_2$ and $PrNi_2$ on the basis of the s-f exchange model. (12 refs.) *A.T.*

72596 Exchange interaction in oxygen-bridged dimers of copper (II) with aromatic *N*-oxides. I. Method of calculation and application to di-μ-(pyridine *N*-oxide)-bis [dichlorocopper(II)]. S.F.A.Kettle, G.R.Tsaparlis (School of Chem. Sci., Univ. of East Anglia, Norwich, England).
J. Chem. Phys. (USA), vol.78, no.8, p.5004-12 (15 April 1983).
A method, based on the Dirac-Van Vleck-Serber permutation degeneracy model, for the estimation of the exchange integral J in oxygen-bridged dimers of copper (II) with aromatic *N*-oxides is demonstrated for the case of the dimer di-μ-(pyridine *n*-oxide)-bis (dichlorocopper II), $[(C_6H_5NO)CuCl_2]_2$. The calculations are limited to the planar three-center, four-electron system Cu(↑)-O(↑↓)-Cu(↑), with due account of the second bridging oxygen and all omitted atoms or electrons. The computational details and approximations are discussed. It is found that J is sensitive to the structural data, the atomic orbitals and functions used, the ionic state of copper, and configuration interaction (inclusion of excited, charge-transfer configurations). The exchange interaction is mediated by a σ superexchange pathway, all π pathways being excluded. Finally, both the oxygen 2*s* and 2*p* orbitals contribute to J. (56 refs.)

75.30G Anisotropy

72597 Magnetic anisotropy in $(Fe,Co)_{75}Si_{15}B_{10}$ and $(Fe_{0.11}Co_{0.89})_{72}Mo_3Si_{15}B_{10}$ metallic glass ribbons, induced by constant stress and constant strain annealing. O.V.Nielson, L.K.Hansen (Dept. of Electrophys., Tech. Univ. of Denmark, Lyngby, Denmark), A.Hernando, V.Madurga.
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.73-80 (April 1983).
The magnetic anisotropy induced by constant tensile stess and constant torsional strain annealing has been studied for liquid quenched alloys of the compositions $(Fe_xCo_{1-x})_{75}Si_{15}B_{10}$ (x=0.1-1.0) and $(Fe_{0.11}Co_{0.89})_{72}Mo_3Si_{15}B_{10}$. Within a certain annealing temperature range (depending on composition, pre-annealing time, applied stress and stress-annealing duration) the induced easy axis is perpendicular to the ribbon axis. After subsequent stress relief the easy axis turns parallel to the ribbon axis. The easy ribbon axis anisotropy produced in this way reveals a similar composition dependence as the anisotropy obtained by magnetic field annealing but the anisotropy constant may be up to one order of magnitude larger, depending on the stress annealing conditions. In contrast to the field anneal induced anisotropy, the stress anneal induced anisotropy can be made permanent in the sense that it still remains after subsequent stress relief. It is furthermore shown that constant strain annealing induced anisotropy can be deduced from the properties observed after constant stress annealing, and a method for selecting proper stress relaxation conditions, with the purpose of obtaining maximum magnetic softness (isotropy) is proposed. (15 refs.)

72598 Separation into two contributions of stress anneal induced magnetic anisotropy in metallic glass ribbons. O.V.Nielsen (Dept. of Electrophys., Tech. Univ. of Denmark, Lyngby, Denmark).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.81-5 (April 1983).
Stress annealing experiments followed by stress relief experiments on metallic glass ribbons have made it possible quantitatively to separate the stress anneal induced magnetic anisotropy K_u into the terms of opposite sign, K_{an} and K_{pl}. These terms, labelled anelastic and plastic, respectively, show very different dependences on the annealing conditions. The measurements of K_u of either sign were made possible by use of the small signal inverse Wiedemann effect in twisted ribbons as recently described. (20 refs.)

75.30H Magnetic impurity interactions

72599 Impurity atom with an easy-plane anisotropy in a ferromagnet with an easy-axis anisotropy and ferromagnetic resonance. A.I.Lukanin, M.V.Medvedev (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.441-9 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An analysis is made of a Heisenberg ferromagnet with a single-ion anisotropy of the easy-axis type containing magnetic impurity ions with a single-anisotropy of the easy-plane type. It is shown that a certain number of spin deviations from the state of an ideal parallel alignment of the impurity and matrix spins may occur in the ground state. Moreover, impurity spins with the easy-plane anisotropy can give rise to discrete energy levels in the gap of the spin-wave spectrum. These levels correspond to spin excitations of two types; one which reduces the spontaneous magnetization of a crystal, whereas the other increases such magnetization. A study is made on how ferromagnetic resonance can be used to distinguish these types of spin excitation. (9 refs.) *A.T.*

Critical behaviour of the correlation function of the Ising model with impurity bonds ....See Entry 72626

75.30K Magnetic phase boundaries

(inc. magnetic transitions, metamagnetism, etc)

72600 Model of magnetic phase transition in a monolayer of molecules that are chemosorbed on the surface of a nonmagnetic metal. V.D.Borman, L.A.Maksimov, A.P.Popov, V.I.Troyan (Moscow Engng. Phys. Inst., Moscow, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.49-53 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1269-74 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors consider the magnetic phase transition in a molecular monolayer on the surface of a nonmagnetic metal. To describe the experimental findings, the authors modify Kittel's model, taking account of the temperature dependence of the magnetic moments of the sublattices and the case of different filling numbers for the sublattices. To correctly allow for these relationships, they employ the Hamiltonian in Kittel form and they obtain a model expression for the free energy within the framework of molecular field theory. (9 refs.)

72601 Effect of pressure on the Curie temperature of $CuCr_2Se_{4-x}Br_x$. T.Kanomata (Dept. of Appl. Phys., Tohoku Gakuin Univ., Miyagi, Japan), K.Shirakawa, T.Kaneko.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1387-93 (April 1983).
The pressure derivative of the Curie temperature $\partial T_c/\partial p$ of $CuCr_2Se_{4-x}Br_x$ ($0.0 \leq x \leq 1.0$) have been obtained from the results of measurement of temperature dependence of initial permeability (μ) at various pressures. The Curie temperature decreases linearly with pressure for all of as-prepared samples. The magnitude of the negative value of $\partial T_c/\partial p$ for $CuCr_2Se_{4-x}Br_x$ decreases with increasing Br content from -1.67K/kbar at x=0.0 to -0.35K/kbar at x=0.8. The pressure effect on the magnetisation of $CuCr_2Se_{4-x}Br_x$ has also been studied by the forced magnetostriction. On the basis of these results, the composition dependences of the Curie temperature, the magnetisation and the exchange interaction are determined. Moreover, the strain dependence of the exchange interaction is also obtained. The exchange striction is also studied for $CuCr_2Se_{3.5}Br_{0.5}$. (18 refs.)

72602 Magnetic relaxation measurements in FeCr alloys. A.C.Palumbo (Dept. of Phys., Univ. of Rochester, Rochester, NY, USA), R.D.Parks, Y.Yeshurun.
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.66-72 (April 1983).
Detailed magnetic measurements are presented for Fe_xCr_{1-x}, $0.12 \leq x \leq 0.24$. The authors focus on irreversible phenomena and present magnetic viscosity measurements for external magnetic fields 100 Oe$\leq H \leq$3 kOe, in the temperature range 1.5K$\leq T \leq$7.5K. They find the border lines of the spin-glass phase via the disappearance of irreversible relaxation and construct a magnetic phase diagram for FeCr in the *H-T-x* space. (20 refs.)

72603 Magnetic transition state approach to ferromagnetism of metals:Ni. A.I.Liechtenstein, V.A.Gubanov (Inst. for Chem., Sverdlovsk, USSR), M.I.Katsnelson, V.I.Anisimov.
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.125-30 (April 1983).
The generalization of Slater's magnetic transition state approach of the case of continuous energy distribution of d-states in metals is suggested. The method developed allows the first-principle calculations of local spin excitation energies. The connection of these magnetic excitations to the spin-wave spectrum and Curie temperature T_c for an arbitrary type of magnetic interaction is established. Using the X_α-SW cluster method with k-dependent boundary conditions the numerical calculations of magnetic excitation energies and T_c for Ni have been carried out in very reasonable agreement with experimental values available. (22 refs.)

72604 A Mossbauer study of the variation in Neel temperature in iron-rare earth layer compounds. J.A.Birch, M.F.Thomas (Oliver Lodge Lab., Univ. of Liverpool, Liverpool, England).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.141-50 (April 1983).
A Mossbauer study of the layer compounds $Sr_{1/2}La_{3/2}Li_{1/2}Fe_{1/2}O_4$, $Sr_{1/2}Pr_{3/2}Li_{1/2}Fe_{1/2}O_4$, $Sr_{1/2}Nd_{3/2}Li_{1/2}F_{1/2}O_4$ which contain iron in a tetravalent state, measured their Neel temperatures as (29.2±1)K, (29.2±1)K and (35.2±1)K, respectively. These values of Neel temperature are discussed in terms of interlayer separation and the magnetic nature of the interlayer rare earth ions. (4 refs.)

72605 Experimental curves of entropy and susceptibility versus temperature for copper nuclear spins down to the ordered state. M.T.Huiku, T.A.Jyrkkio, M.T.Loponen (Low Temperature Lab., Helsinki Univ. of Technol., Espoo, Finland).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1516-19 (9 May 1983).
The entropy and susceptibility of copper nuclear spins below 1 μK have been measured as a function of temperature both in the paramagnetic and in the antiferromagnetic states. The critical temperature is 63±10 nK, about 30% of the mean-field estimate. The results are in agreement with calculations based on the spin-wave spectrum of the dipolar and the Ruderman-Kittel interactions in the FCC lattice of copper. (15 refs.)

72606 High-pressure and extended X-ray-absorption fine-structure study of Cr-rich Cr-Ge alloys. R.Munch, H.D.Hochheimer, A.Werner (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany), G.Materlik, A.Jayaraman, K.V.Rao.
Phys. Rev. Lett. (USA), vol.50, no.20, p.1619-22 (16 May 1983).
From the pressure dependence of the Neel temperature (T_N) in Cr-Ge alloys, the antiferromagnetic transition is found to be the commensurate state, when Ge is greater than 0.6 at.%. The present extended X-ray absorption fine-structure study on Cr-Ge shows clearly that Ge goes substitutionally into the Cr lattice. On the basis of the rigid-band model this can be understood only if Ge acts as an electron donor to the d band of Cr. These findings raise the interesting question as to how Si and Ge additions stabilise the commensurate phase, despite their smaller e/a ratio. (16 refs.)

72607 Phase transitions in random anisotropy magnets. M.J.O'Shea, S.G.Cornelison, Z.D.Chen, D.J.Sellmyer (Behlen Lab. of Phys., Univ. of Nebraska Lincoln, NE, USA).
Solid State Commun. (USA), vol.46, no.4, p.313-16 (April 1983).
The authors report a study of magnetic properties and phase transitions in random anisotropy glasses rich in the rare-earth elements Gd, Tb and Nd. For the Gd glass, which has a small magnetic anisotropy, they find an extremely large, possibly infinite, susceptibility below 120K and no intrinsic spontaneous magnetization. Below 55k an hysteretic state develops. The Tb and Nd glasses, both of which have large anisotropy, exhibit transitions to a speromagnetic state and they do not show an infinite susceptibility phase. The results are discussed in terms of recent theoretical predictions concerning phase transitions in the presence of random magnetic anisotropy. (13 refs.)

75.40 CRITICAL-POINT EFFECTS, SPECIFIC HEATS, SHORT-RANGE ORDER

(inc. spin glasses)

72608 Spin-glass with short-range interaction induced by an electromagnetic field in semiconductors. I. Low temperatures domain. M.Crisan, Z.Gulacsi, M.Gulacsi (Dept. of Phys., Cluj Univ., Cluj, Rumania).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.47-55 (April 1983).
The spin-glass state which occurs due to the spin-spin interaction induced by an electromagnetic field in semiconductors is analyzed on the base of the Abrikosov-Moukhin model. The specific heat and the magnetic susceptibility are calculated at low temperatures on the two domains. The matching between these domains has been explained and the matching temperature has been calculated. The domain near the critical temperature has been treated using the percolation model. (4 refs.)

72609 Neutron scattering in insulating semi-spin glass. G.Gavoille (Lab. d'Electrite et d'Automatique, Faculte de Sci., Nancy, France), J.Hubsch.
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.89-94 (April 1983).
A semi-spin glass which consists of a *Z* ferro, antiferro or ferrimagnetic spin component and of *X-Y* spin glass component, exhibits a very specific neutron diffraction pattern looking like very broad Bragg reflections. Experimental data are compared to theoretical estimations. (6 refs.)

72610 The Invar effect and spin fluctuations in disordered Fe$_3$Pt. K.R.A.Ziebeck (Inst. Laue Langevin, Grenoble, France), P.J.Webster, P.J.Brown, H.Capellmann.
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.151-9 (April 1983).
Below 297K chemically disordered Fe$_3$Pt orders ferromagnetically with a moment per formula unit of 8.6 μ_B at 4.2K. Above the Curie temperature the inverse static susceptibility varies linearly with temperature. These observations are at variance with recent models of the Invar effect which assume an instability of the iron moment in the FCC lattice. Paramagnetic scattering experiments, using polarised neutrons and polarisation analysis in the paramagnetic phase of Fe$_3$Pt reveal significant magnetic scattering which is peaked in the forward direction. The spatial correlations which give rise to the forward scattering are of a predominantly ferromagnetic nature extending over approximately 12-16 Å and persist above 2.65 T_C. Integration of the paramagnetic response over an inverse atomic volume yields a moment per iron atom of 2.18 μ_B at 1.33 T_C which reduces to 1.73 μ_B at 2.65 T_C. The spatial correlations are of paramount importance in characterizing the paramagnetic properties of Fe$_3$Pt and must therefore be considered in any discussion of the static susceptibility and Invar properties. (21 refs.)

72611 Observation of quantum fluctuations in FeSi. K.R.A.Ziebeck, H.Capellmann, P.J.Brown, P.J.Webster (Inst. Laue Langevin, Grenoble, France).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.160-4 (April 1983).
Polarised neutrons and polarisation analysis have been used to determine the diffuse magnetic scattering from FeSi as a function of temperature. The variation of the scattering as a function of *Q* is indicative of spatial correlations of magnetic moment extending over several interatomic distances. At 100K the correlations are predominantly antiferromagnetic in character, but become increasingly ferromagnetic with increasing temperature. It is the thermal variation of these correlations which gives the unusual temperature dependence of the static susceptibility. The amplitude of the moment, estimated by integrating of observed response over an inverse atomic volume, was found not to vary significantly with temperature. A quantitative interpretation of these results is given in terms of a model in which FeSi shows properties of a heavy Fermi liquid. (14 refs.)

72612 Spin glass behavior of some rapidly quenched iron (2+) aluminosilicates. A.Schnell, J.C.Bernier (Dept. Sci. des Materiaux, ENSCS, Strasbourg, France), J.P.Sanchez.
Mater. Res. Bull. (USA), vol.18, no.3, p.251-5 (March 1983).
Reports on the magnetic and structural properties of ferrous iron aluminosilicate glasses investigated by DC susceptibility, magnetization and ^{57}Fe Mossbauer measurements. (8 refs.)

72613 An order parameter theory on the frequency-dependent susceptibility of spin glasses. K.Honda (Dept. of Appl. Phys., Nagoya Univ., Nagoya, Japan).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.179-82 (25 April 1983).
By making use of the free energy given in a previous paper, conventional kinetic equations for order parameters and for what was named an internal field parameter are investigated to calculate the dynamical susceptibility. The significant features observed in recent experiments are described successfully. (11 refs.)

72614 Speckle picture of spin-glasses and inhomogeneous mean field theory. J.R.Provost, G.Vallee (Phys. Theorique, IMSP Univ. de Nice, Nice, France).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.183-5 (25 April 1983).
The authors show that the mean field $H(r)$ is an order parameter for spin-glasses. It has a 'speckle' type spatial dependence. The difference between the critical temperatures for the specific heat and the magnetic susceptibility is explained in terms of inhomogeneous solutions of the equation for H in a speckle. (7 refs.)

72615 Competing ferromagnetic and spin-glass order in a *Au*Fe alloy. I.A.Campbell, S.Senoussi (Lab. de Phys. des Solides, Univ. Paris-Sud, Orsay, France), F.Varret, J.Teillet, A.Hamzic.
Phys. Rev. Lett. (USA), vol.50, no.20, p.1615-18 (16 May 1983).
Magnetic and Mossbauer measurements on a *Au*-19-at.%-Fe alloy are reported. After ferromagnetic ordering at $T_c \simeq 170$K, spin-glass-like transverse ordering sets in below $T \simeq 15$K. This behaviour is consistent with the predictions of a Heisenberg mean-field model, in which the transverse ordering transition is distinct from a crossover to strong irreversibility. (23 refs.)

72616 Evolution from ferromagnetism to spin-glass behavior. J.W.Lynn, R.W.Erwin (Dept. of Phys., Univ. of Maryland, College Park, MD, USA), H.S.Chen, J.J.Rhyne.
Solid State Commun. (USA), vol.46, no.4, p.317-20 (April 1983).
The magnetic properties of amorphous (Fe$_x$Ni$_{100-x}$)$_{75}$p$_{16}$B$_6$Al$_3$ have been investigated in the critical concentration region ($x_c = 17$) via neutron scattering. For $x > x_c$ a transition to ferromagnetism is first observed followed at lower temperatures by an evolution to spin-glass behavior. Associated with this low temperature state are two distinct time scales corresponding to a resolution-limited elastic peak and to excitations. The temperature dependence of the elastic component is directly related to the spin-glass order parameter and indicates that there is a region of temperature where ferromagnetism and spin-glass order coexist. (19 refs.)

72617 Heat capacity of alloys with interacting magnetic-order parameters. N.I.Kourov, Yu.N.Tsiovkin, S.M.Podgornykh, N.V.Volkenshtein (Inst. of Metal Phys., Acad. of Sci., USR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.367-70 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.662-7 (Aug. 1982). [received: May 1983]
The heat capacity C_p of (Pd$_x$Pt$_{1-x}$)$_3$Fe alloys ordered in an FCC lattice is investigated in the temperature interval 20-300K at a concentration phase transition from the ferromagnetic (F) state at $x=1$ into the antiferromagnetic (AF) at $x=0$. The concentration and temperature dependences of C_p are discussed with account taken of the experimentally reconstructed magnetic-state diagram of these alloys. It is shown that the observed singularities of $C_p(T,x)$ are due mainly to the change of the magnetic state of the alloy. The possible type of polycritical points that appear on the phase transition line with respect to the antiferromagnetic order parameter is analyzed. (19 refs.)

75.40D Ising and other classical spin models

72618 Antiferromagnetic triangular Ising model: an exact calculation of *P*(*h*). T.C.Choy, D.Sherrington (Phys. Dept., Imperial Coll., London, England).
J. Phys. A (GB), vol.16, no.8, p.L265-8 (1 June 1983).
Using exact results for the nearest-neighbour two, four and six spin correlations, the authors have evaluated the local field probability distribution function $P(h)$ for the (fully frustrated) triangular antiferromagnetic Ising lattice in its ground state. (20 refs.)

72619 Frustrated Ising chains. IV. B.G.S.Doman, M.A.Z.Habeeb (Dept. of Appl. Math. & Theoretical Phys., Univ. of Liverpool, Liverpool, England).
J. Phys. C (GB), vol.16, no.13, p.2591-601 (10 May 1983).
The methods of Williams (1981) and Doman and Williams (1982) are used in investigating the ground-state and low-temperature properties of an Ising chain with bonds which are successively ferromagnetic or antiferromagnetic at random. If the ferromagnetic bonds are stronger than the antiferromagnetic ones, the properties are essentially the same as when they have the same strength. If the ferromagnetic bonds are weaker, there is a step in the magnetisation when the magnetic field is equal to the difference in the strengths of the ferro- and antiferromagnetic bonds. For smaller magnetic fields all the frustrated bonds are ferromagnetic. Further steps in thermodynamic properties occur for values of magnetic field B=the ferromagnetic bond strength ×2/integer. (6 refs.)

72620 Spin glasses with RKKY-type interactions; numerical studies on small samples. C.Bergonzoni (Istituto di Fisica, Univ. di Modena, Modena, Italy), G.Lo Vecchio, G.Morandi.
Lett. Nuovo Cimento (Italy), vol.37, ser.2, no.2, p.71-6 (14 May 1983).
The authors perform a systematic numerical study of spatially-disordered models of spin-glasses with interactions of the RKKY type. A finite model is used, in which $S=9$ Ising spins are randomly distributed on a $9\times9\times9$ simple cubic lattice. Results for the order parameter on a finite sample and in mean-field theory are presented. (10 refs.)

72621 First-order phase transitions in Potts and Ising systems. J.Bricmont (Inst. de Phys. Theorique, Univ. de Louvain, Louvain-la-Neuve, Belgium), J.L.Lebowitz, A.Messager.
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.169-72 (25 April 1983).
The authors use an equivalence between the q-state Potts model on a d-dimensional lattice for $q=2^n$, $n=1, 2, \ldots$ and a spin 1/2 Ising model on n copies of the lattice with 2 n-spin ferromagnetic interactions to obtain some exact new results for both systems. In particular they prove the existence of first-order phase transitions for a class of ferromagnetic Ising systems obtained as perturbations of the large q Potts-Ising system and the non-vanishing of the surface tension for the Potts model (with $q=2^n$) at all temperatures below their transition temperature. (13 refs.)

72622 Analyticity of the free energy of the two-dimensional random Ising model. H.Nishimori (Serin Phys. Lab., Rutgers Univ., Piscataway, NJ, USA).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.303-4 (9 May 1983).
It is shown that the systematic-expansion method of the free energy of the two-dimensional random Ising model, by Hoever and Zittartz (1982), does not lead to evidence for the absence of a spin glass transition as they claimed. (4 refs.)

72623 One-dimensional Ising model in a random field. R.Bruinsma (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA), G.Aeppli.
Phys. Rev. Lett. (USA), vol.50, no.19, p.1494-7 (9 May 1983).
The one-dimensional Ising model in a random field is studied with use of a functional recursion relation. For temperatures exceeding a given value, the fixed function of the relation is found and shown to be a devil's staircase. From this result it is possible to evaluate the free energy to arbitrary precision. In the field-strength-temperature plane, a crossover line corresponding to the onset of frustration is found. (10 refs.)

72624 Static and dynamic critical magnetic fields in Ising spin-glasses. W.Kinzel, K.Binder (Inst. fur Festkorperforschung, Kernforschungsanlage Julich, Julich, Germany).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1509-11 (9 May 1983).
By Monte Carlo simulations it is shown that the magnetization $M(t,H)$ of the two-dimensional nearest-neighbor Edwards-Anderson model is proportional to H^{1-x}, essentially independent of temperature T, for fields $H<H_c^{eq}(T)$, with $H_c^{eq}(T)\propto T^{1/x}$, the exponent being $x\approx0.28\pm0.06$. Irreversible behavior on a time scale t sets in for a field $H_c(t)$ where $H_c(t)/T_f(t)$ nearly follows the De Almeida-Thouless line, although no static nonzero freezing temperature T_f exists. Consequences for the interpretation of related experimental work are discussed. (23 refs.)

72625 Dynamics of the infinite-range Ising spin glass. K.H.Fischer (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany).
Solid State Commun. (USA), vol.46, no.4, p.309-11 (April 1983).
The Glauber dynamics of an Ising spin glass with infinite-range interactions and additional static field, h, is investigated near the freezing temperature, T_f. The author obtains critical slowing down at and below the de Almeida-Thouless instability line (1978), $h_c(T)$, to order $(1-T/T_f)^3$ with algebraic decay of the spin correlations $\sim t^{-\nu}$, where $\nu=1/2$ at T_f and $\nu\leq1/2$ for $T<T_f$. (25 refs.)

72626 Critical behaviour of the correlation function of the Ising model with impurity bonds. V.S.Dotsenko, V.S.Dotsenko (L.D. Landau Inst. of Theoretical Phys., Acad. of Sci., USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.406-14 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.727-42 (Aug. 1982). [received: May 1983]
The authors consider a two-dimensional Ising model with a small impurity bond concentration. At the phase transition point they evaluate exactly the correlation function $\Gamma(R)\equiv\langle\sigma(0)\sigma(R)\rangle$. In contrast to the pure Ising model, where $\Gamma(R)\propto R^{-\zeta}$, $\zeta={}^1/_4$, the exponent ζ of the correlator turns out to be equal to zero when there are impurity bonds present. At distances $R\gg r_i\propto e^{1/\nu}$, where $\nu\ll1$ is the impurity bond concentration, $\Gamma(R)$ is a function which varies much more weakly than a powerlaw function. (12 refs.)

75.40F Heisenberg and other quantized spin models

72627 On the zero-temperature critical behaviour of the quantum *X-Y* model in a transverse magnetic field. T.K.Kopec, G.Kozlowski (Inst. for Low Temperature & Structure Res., Polish Acad. of Sci., Wroclaw, Poland).
Phys. Lett. A (Netherlands), vol.95A, no.2, p.104-6 (18 April 1983).
It is shown that the zero-temperature critical behaviour of the quantum-mechanical *X-Y* spin model in a transverse magnetic field is characterized by pure gaussian critical exponents. Remarks on the universality of the quantum critical behaviour are also made. (14 refs.)

72628 Critical dynamics at the percolation threshold by fractal and scaling approaches. C.K.Harris, R.E.Stinchcombe (Dept. of Theoretical Phys., Oxford Univ., Oxford, England).
Phys. Rev. Lett. (USA), vol.50, no.18, p.1399-402 (2 May 1983).
The critical dynamics of Heisenberg spin systems at the percolation threshold is obtained from the transformation of the equations of motion under a length scaling achieved by elimination of sites. The method is applied exactly to d-dimensional nonrandom fractals representing the infinite-cluster backbone and approximately to a truly random two-dimensional system to yield dynamic scaling forms for response function and characteristic frequency, and associated static and dynamic critical exponents. (18 refs.)

72629 Topological phase transition in the *XY* model of a spin glass. I.E.Dzyaloshinskii, S.P.Obukhov (L.D. Landau Inst. of Theoretical Phys., Acad. of Sci., USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.456-66 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.813-32 (Aug. 1982). [received: May 1983]
The Villain variant of the XY model of a spin glass is considered in the three-dimensional case. It is shown that there occurs in the system of topological phase transition connected with the appearance of frustration lines of infinite length. In the phase thus produced, the correlation distance at zero temperature is infinite. At any finite temperature, however, the correlation has a finite range. The possibility of generalization to the Heisenberg model of spin glasses is discussed. (21 refs.)

75.60 DOMAIN EFFECTS, MAGNETIZATION CURVES, AND HYSTERESIS

75.60C Domain walls and domain structure

(for magnetic bubbles, see 75.70K)

72630 Changes in the magnetic properties of amorphous alloy $Fe_5Co_{70}Si_{15}B_{10}$ caused by thermomagnetic treatment and the dependence of these changes on the initial state of alloy. I.B.Kekalo, V.L.Stolyarov, V.E.Taranichev, V.Yu.Tsvetkov (Inst. of Steels & Alloys, Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.484-90 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The initial state of $Fe_5Co_{70}Si_{15}B_{10}$, controlled by preliminary heat treatments, exerted a strong influence on the kinetics of changes of its magnetic properties and on the degree of such changes. When the domain structure was stabilized by a preliminary heat treatment because of local directional ordering, the rate of change of B_r/B during thermomagnetic treatment was small and the value of μ_0 varied following a curve with a maximum. In the absence of domain wall stabilization the value of μ_0 decreased monotonically. The best properties were obtained by high-temperature annealing in the absence of a magnetic field and subsequent cooling in water; thermomagnetic treatment at 270°C caused deterioration of the properties. (22 refs.) *A.T.*

72631 Frequency dependent damping and stiffness of the domain walls in pure iron-deficient polycrystalline YIG. M.Guyot, T.Merceron, V.Cagan (Lab. de Magnetisme, CNRS, Meudon, France).
J. Phys. D (GB), vol.16, no.5, p.L193-6 (14 May 1983).
Very large partial relaxations due to diffusion after-effects are observed in the initial permeability frequency spectrum of undoped but slightly iron-deficient YIG polycrystals. Dynamic changes of the domain wall parameters, associated with the diffusant relaxations, are introduced to explain the observations. (8 refs.)

72632 Effect of priming layer on magnetic losses in anisotropic high-permeability electrical steel. V.M.Segal, Yu.N.Starodubtsev, T.I.Prasova, M.Ya.Sokolovskii, M.B.Tsyrlin (Verkhne-Isetsk Metall. Plant, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.197-200 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1423-6 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
When the quality of the surface prior to formation of the primer layer is high, the layer exerts an overall positive effect on losses in specimens with high magnetic induction as a result of the tensile stress created by the priming layer itself. In specimens with a moderate degree of perfection of the texture (B_{2500}~1.9 T), even a not very well developed primer/metal interface has a negative effect on losses, one that cannot be compensated for by tensile stresses in this case. Moreover, in the case of a diffuse final texture, the magnetic losses of a specimen with a defect-free priming layer are degraded when tensile stresses are applied. (5 refs.)

72633 Magnetic properties of the compound $HfFe_2Si_2$. R.V.Skorozda, Yu.V.Stadnyk, Yu.K.Gorelenko, Ya.P.Yarmolyuk, S.B.Kruglyashov (Ivan Franko State Univ., Lvov, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.479-83 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An investigation was made of the magnetization, magnetic susceptibility, electrical resistivity, and thermoelectric power of $HfFe_2Si_2$ (space group Pbcm; a=0.7464 nm, b=0.7006 nm, c=0.5067 nm) at temperatures 4.2-1100K. The compound $HfFe_2Si_2$ was found to be ferrimagnetic ($T_c \approx 410K$) with different magnetic moments of the iron atoms in the 4(d) and 4(f) positions. A transition from a noncollinear to a collinear ferrimagnetic state took place at 190K. Up to 750K the paramagnetic susceptibility was described by the Neel law for a two-sublattice ferrimagnet; above this temperature there was a change in the energy band structure of the compound. (6 refs.) *A.T.*

72634 Magnetic properties of $Pr_xY_{1-x}Co_5$ and $Pr_xSm_{1-x}Co_5$ crystals. A.S.Ermolenko (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.503-9 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The magnetic moments and the angles between the easy magnetization direction and the c axis were determined for $Pr_xY_{1-x}Co_5$ single crystals at temperatures 4.2-300K. The magnetization curves in magnetic fields up to 7×10^6 A/m were determined along the *a*, *b*, and *c* axes at 4.2K. These curves were then used to find the anisotropy constants of the Pr sublattice and the molecular field of the intersublattice exchange interaction. The parameters used to calculate the magnetization curves of $Pr_xSm_{1-x}Co_5$ alloys were also determined. (11 refs.) *A.T.*

72635 The saturation magnetization of some substituted Fe-Si-B metallic glasses. II. K.Hoselitz (School of Engng. & Appl. Sci., Univ. of Sussex, Brighton, England).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.39-46 (April 1983).
For pt.I see ibid., vol.20, p.201 (1980). Variations of the magnetic moment n_B of the Fe-atom in 80-20 Fe-metalloid metallic glasses are measured. For Cu, n_B shows at first a small rise followed by a fall to a constant value. In the case of Cr, n_B at first stays constant and then decreases almost linearly. These results suggest that the magnetism of these materials is of the electron band type. (9 refs.)

72636 Magnetic properties of $REFe_2Si_2$ compounds. A.M.Umarji, D.R.Noakes, P.J.Viccaro, G.K.Shenoy, A.T.Aldred (Argonne Nat. Lab., Argonne, IL, USA), D.Niarchos.
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.61-5 (April 1983).
Structural, magnetization and Mossbauer measurements are reported on $REFe_2Si_2$ (RE=La, Ce, Nd, Gd, Er). In contradiction with earlier reports, all these compounds contain only one type of Fe atom with no magnetic moment on it. The antiferromagnetic phase of Nd, Gd and Er compounds produces hyperfine magnetic fields at half of the Fe sites and no field at the other half. This permits us to predict the antiferromagnetic structure. La and Ce compounds show weak paramagnetic behavior indicating tetravalent Ce and trivalent La atoms in these structures. (19 refs.)

72637 Stoner excitations in the strong itinerant amorphous ferromagnets $Fe_xNi_{80-x}BI_{18}Si_2$ and $Fe_{80}B_{20}$. E.Babic, Z.Marohnic (Inst. of Phys., Univ. of Zagreb, Zagreb, Yugoslavia), E.P.Wohlfarth.
Phys. Lett. A (Netherlands), vol.95A, no.6, p.335-8 (9 May 1983).
Accurate measurements of the static magnetization of the amorphous ferromagnets $Fe_xNi_{80-x}B_{18}Si_2$ (x=15, 20, 40, 60%) and $Fe_{80}B_{20}$ are reported. The results are analyzed in terms of spin-wave and Stoner excitations, and the latter indicate strong itinerant ferromagnetism with a Stoner gap Δ varying between 20 and 60K. The other fitting parameters give values of the spin-wave stiffness and a quantity simply related to the saturation magnetization. The well-known anomaly regarding the spin-wave stiffness observed in earlier measurements is thus explained quantitatively. (11 refs.)

75.60G High coercivity materials

72638 Study of the high-temperature X-ray diffraction of a Fe-Cr-Co permanent magnetic alloy. Tang Di-sheng, Zhang Yu-ling, Yi Sun-Sheng, Lin Wen-Gui, Li Guo-Dong (Inst. of Phys., Acad. Sinica, Shanghai, China).
Chin. Phys. (USA), vol.3, no.1, p.9-13 (Jan.-March 1983). [received: May 1983]
A fabricable permanent magnetic alloy, with composition of 62Fe-23Cr-15Co (in wt.%) has been studied by a high-temperature X-ray diffraction method. Debye-Scherrer photographs of samples treated with aging in a magnetic field and also of those treated without a magnetic field were taken. It has been observed that the transformation process with rising temperature up to 800°C is different in the two classes of samples. The lattice parameters of the samples without a treatment in a magnetic field have been measured at various temperatures, and it has been found that in these samples a transitional phase unknown before appeared at 610°C, which was unstable at other temperatures. (8 refs.)

72639 Structure formation in and magnetic properties of a P/M iron-chromium-cobalt alloy. Yu.G.Dorofeev, V.V.Kulikov, B.P.Adrianovskii (Novocherkassk Polytech. Inst., USSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.734-6 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.60-3 (Sept. 1982). [received: March 1983]
A study was made of the dependence of the processes of structure formation in a P/M iron-chromium-cobalt alloy on heat treatment conditions. Optimum magnetic properties were attained after 3-h sintering at a temperature of 1290 ± 10°C, TMT, and stepwise tempering. It is concluded that the alloy investigated and the process developed can be employed for the industrial manufacture of permanent magnets. (5 refs.)

75.60J Fine-particle systems

72640 The magnetostatic energies of ellipsoidal particles which contain a reverse domain and a nonmagnetic inclusion. J.E.Coleman (Dept. of Appl. Phys., Conventry Lanchester Polytech., Coventry, England).
J. Phys. D (GB), vol.16, no.5, p.909-13 (14 May 1983).
A superposition method is used to obtain expressions for the changes of magnetostatic energy when a reverse domain is formed either adjacent to or surrounding a nonmagnetic inclusion. It is shown that such inclusions may lower the energy barriers to the nucleation of reverse domains and may also hinder the achievement of true saturation. (2 refs.)

72641 Magnetic evidence for the existence of RCo_z with $z \approx 7$ (R=La, Ce, Pr and Nd). H.O.Gupta, W.E.Wallace, R.S.Craig (Dept. of Chem., Univ. of Pitsburgh, Pittsburgh, PA, USA).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.95-7 (April 1983).
RCo_5 alloys (R=La, Ce, Pr, Nd, Sm and Y) in fine particle form were examined magnetically. The cast materials were observed to develop additional phases during comminution by ball milling. The compositions of the phases were inferred from the measured Curie temperatures. A component having a Curie temperature between those of RCo_5 and R_2Co_{17} was present in the fine powders and was identified as R_3Co_{22} or R_4Co_{27}. A component in the La-Co system having $T_c \approx 825$°C was identified as La_2Co_{17}. The R_3Co_{22}, R_4Co_{27} and La_2Co_{17} compounds, which have not been reported previously, are apparently formed from the RCo_5 compounds during the comminution process. There is no evidence of the formation of these phases for R=Rm or Y. (6 refs.)

72642 Superparamagnetism in γ-Mn_2O_3-α-Fe_2O_3-α-Mn_2O_3 system. B.Banerjee, S.Lahiry (Dept. of Chem., Univ. of Delhi, Delhi, India).
Phys. Status Solidi a (Germany), vol.76, no.2, p.683-94 (16 April 1983).
Superparamagnetism is observed in the mixed system, γ-Mn_2O_3-α-Fe_2O_3-α-Mn_2O_3 prepared by ceramic technique and the salient characteristics of a superparamagnetic substance are studied. The magnetic granulometry method (Langevin function) is employed to derive useful results like particle diameter (lying between 100 to 150 Å), number of particles per gram, magnetic moment per particle, and number of unique atoms per particle (N). These samples obey a $CaN^{0.56 \text{ to } 0.60}$ relationship. Following Neel's criterion of a superparamagnet, the particle diameters are expected to be above 100 Å. X-ray line broadening method yields a diameter of 150 Å, while electron micrographs show agglomeration of the particles. Neither γ-Mn_2O_3 nor α-Fe_2O_3 nor α-Mn_2O_3 itself, under identical preparation conditions, exhibit superparamagnetism like the mixed system, γ-Mn_2O_3-αFe_2O_3-α-Mn_2O_3. (31 refs.)

75.70 MAGNETIC FILMS AND PLATES

72643 The magnetic contribution to specific heat in thin ferromagnetic films. L.Wojtczak, A.Urbaniak-Kucharczyk (Inst. of Phys., Univ. of Lodz, Lodz, Poland), J.Mielnicki, B.Mrygon.
Phys. Status Solidi a (Germany), vol.76, no.1, p.113-20 (16 March 1983).
The magnetic contribution to the specific heat of thin ferromagnetic films is discussed. The numerical calculations made for the special case of SC crystallographic lattice and $S=1/2$ reveal that the specific heat is larger in thin films than in bulk material, contrary to the behaviour of other properties, e.g. magnetization or electrical resistivity. (5 refs.)

72644 Magnetic and electronic properties of thin iron oxide films. M.Domke, B.Kyvelos, G.Kaindl (Freie Univ. Berlin, Berlin, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.727-32 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Conversion electron Mossbauer spectroscopy (CEMS) with the 14.4 keV gamma resonance of ^{57}Fe was employed to study uncovered 5 to 50 Å thick iron oxide films grown on single-crystal Fe(110) and Fe(100) substrates under UHV conditions. For both magnetite (Fe_3O_4) and hematite (α-Fe_2O_3) a decrease of the magnetic hyperfine field and of the Mossbauer isomer shift was observed at room temperature with film thicknesses smaller than 20 Å. In addition, the magnetization vector was found to align preferentially normal to the surface with decreasing thickness of the oxide films. (16 refs.)

75.70K Domain structure (magnetic bubbles)

72645 Parametric excitation of inhomogeneous vibrations of domain walls by a high-frequency homogeneous magnetic field. D.I.Sirota, N.P.Kolmakova, L.V.Vasilevskaya (Inst. of Transport Machine Construction, Bryansk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.607-9 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
It is shown theoretically that, above a certain threshold value, a high-frequency homogeneous magnetic field can excite inhomogeneous vibrations at half the frequency of an alternating magnetic field. This theoretical analysis accounts for the reported experimental observation of such vibrations in $(YGd)_3(FeGa)_5O_{12}$ films. (9 refs.) *A.T.*

72646 Wave optical effects in Lorentz microscopic images of magnetic domain walls. S.Tsukahara, H.Kawakatsu (Electrotech. Lab., Ibaraki, Japan).
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.98-110 (April 1983).
Intensity distributions in Lorentz microscopic defocused images of magnetic domain walls were numerically calculated using wave optics. Constants used in the calculation were generalized by the deflection angle ϕ and the wall width $2x_0$ so that the result was able to apply to any magnetic films. 180° walls in amorphous Gd-Fe films were observed by transmission Lorentz microscopy operating at 200 kV in the defocused mode. Numbers of well resolved interference fringes were apparently observed in convergent images when the illumination angle was kept less than about 2×10^{-6} and their intensity varied in consistent way to the calculated images with the defocusing distance. Series of convergent images of each wall were compared with the calculated ones by a through focus fitting method and the deflection angle and the wall width were accurately determined at a time. The measured example for a Gd-Fe film of 510 Å in thickness was $\phi=2.65 \times 10^{-5}$ and $2x_0=1320$ Å. (22 refs.)

72647 Spectrum of magnetization oscillations in a uniaxial ferromagnetic plate. Yu.I.Bespyatykh, I.E.Dikshtein, S.V.Meriakri, V.V.Tarasenko (Inst. of Radio Engng. & Electronics, Acad. of Sci., Moscow, USSR).
Phys. Status Solidi b (Germany), vol.116, no.2, p.607-16 (1 April 1983).
A theoretical investigation is made for the ground state of a ferromagnetic plate in the vicinity of the Curie temperature in a normal magnetic field. It is shown that there can exist either a uniform magnetic state, a strip domain structure, or a hexagonal domain lattice depending on the temperature and the magnetic field. The spectrum of magnetization oscillations in each of the possible states is calculated and the stability regions of different phases are determined. The results are generalized for orientational phase transitions in the uniaxial ferromagnetic plate in a oblique magnetic field. (6 refs.)

72648 Measurement of magnetic bubble domain wall energy density. J.C.Cho (Dept. of Electrical & Computer Engng., Louisiana State Univ., Baton Rouge, LA, USA).
IEEE SOUTHEASTCON '83 Conference Proceedings, Orlando, FL, USA, 11-14 April 1983 (New York, USA: IEEE 1983), p.31-5
Magnetic bubble domain wall energy density was determined by data of measurement of zero field total stripe width, bubble collapse field and collapse diameter. Energy density was also determined by use of material length calculation. Comparing the two methods, the difference is about 5%. (4 refs.)

75.80 MAGNETOMECHANICAL AND MAGNETOELECTRIC EFFECTS, MAGNETOSTRICTION

72649 Magnetostriction of austenite in iron-nickel-manganese alloys and martensitic transition under the action of a strong magnetic field. I.V.Zolotarevskii, V.L.Snezhnoi, L.M.Sheiko (Pedagogical Inst., Zaporozhye, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.548-53 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the bulk magnetostriction of $Fe_{70+x}Ni_{30-2x}Mn_x$ alloys in the paraprocess region (up to 18-24 kOe). It was found that in the case of N24G3 alloys ($x \approx 3$) the magnetostriction of austenite measured at 77K was of the same order of magnitude as the magnetostriction of N30 alloys ($x=0$) at $T=295K$. An estimate was obtained of the bulk deformation of austenite in the investigated alloys near the martensitic point of the athermal reaction in strongly magnetic fields (100-300 kOe). The shift of the martensitic point under the action of strong magnetic fields was attributed not only to the difference between the magnetizations of the γ- and α-phases, but also to the difference between their bulk magnetostrictions. (20 refs.) *A.T.*

72650 Spontaneous volume magnetostriction in $Y(Fe_{1-x}Co_x)_2$ and $Zr(Fe_{1-x}Co_x)_2$. K.Terao, M.Shimizu (Dept. of Appl. Phys., Nagoya Univ., Nagoya, Japan).
Phys. Lett. A (Netherlands), vol.95A, no.2, p.111-14 (18 April 1983).
The spontaneous volume magnetostriction is calculated for $Y(Fe_{1-x}Co_x)_2$ and $Zr(Fe_{1-x}Co_x)_2$ in the simple itinerant-electron model. The density of states for various compositions is calculated by the recursion method. The calculated results on the composition dependence of the spontaneous volume magnetostriction are shown to be consistent with the experimental ones. (15 refs.)

72651 Magnetic interaction in plastically deformed $FePt_3$ alloy. S.Takahashi, K.Ikeda (Faculty of Engng., Iwate Univ., Morioka, Japan).
Phys. Lett. A (Netherlands), vol.95A, no.5, p.247-8 (2 May 1983).
The transition from antiferromagnetic to ferromagnetic coupling by plastic deformation in $FePt_3$ alloy is explained in terms of the dislocation theory with consideration of ferromagnetic and antiferromagnetic Fe-Fe interactions. (5 refs.)

75.90 OTHER TOPICS IN MAGNETIC PROPERTIES AND MATERIALS

72652 Retarded surface modes in an antiferromagnet. F.A.Oliveira (Inst. de Fisica, Univ. Federal Fluminense, Rio de Janeiro, Brazil).
Phys. Lett. A (Netherlands), vol.95A, no.5, p.245-6 (2 May 1983).
The author obtains the dispersion relation for the retarded surface modes in an antiferromagnet for a general propagation direction. (11 refs.)

72653 Ortho-para conversion of hydrogen molecules on magnetic surfaces. Y.Ishii, S.Sugano (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan).
Surf. Sci. (Netherlands), vol.127, no.1, p.21-34 (April 1983).
The theory of the ortho-para conversion of a hydrogen molecule on magnetic surfaces, involving two paths of energy flow into the translational motion of the molecule and the excitation of the substrate spins, is formulated in a compact form to compare with the experimental results of an antiferromagnet, α-Cr_2O_3, and a ferromagnet, EuO. The enhancement of the conversion rate near the critical temperature for α-Cr_2O_3 and the absence of the enhancement for EuO are explained in a semi-quantitative way. (11 refs.)

76.00 MAGNETIC RESONANCES AND RELAXATION IN CONDENSED MATTER; MÖSSBAUER EFFECT

(for measurement techniques, see 07.58)

76.20 GENERAL THEORY OF RESONANCES AND RELAXATION

72654 Theory of spin relaxation in metals. Relaxation time maximum at low temperatures. F.Shibata, Y.Hamano (Dept. of Phys., Ochanomizu Univ., Tokyo, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1410-19 (April 1983).
A general theory of spin relaxation in metals is developed: it is valid for any temperature domain and also for arbitrary magnitude I of a relevant nuclear spin. A multiple-time relaxation process for $I \geq 1$ is completely determined on a microscopic scale. Though the multiple character of the relaxation process for the first moment reveals itself only at low temperatures and/or high magnetic field, it is essential for the fluctuations even in the high temperature domain. At very low temperatures, the relaxation times saturate in contrast to behaviours given by the Korringa relation and a new phenomenon 'relaxation-time-maximum' is found as a function of inverse temperature. A discussion is given to the related experiments. Effects of spin wave excitations on the relaxation process are also discussed. (24 refs.)

72655 Analysis of magnetic resonance line shape under slow molecular motions. N.A.Sergeev, D.S.Ryabushkin (M.V. Frunze State Univ., Simferopol, USSR).
Sov. Phys. J. (USA), vol.25, no.7, p.624-7 (July 1982). Translation of: *Izv. VUZ Fiz. (USSR)*, vol.25, no.7, p.48-52 (July 1982). [received: May 1983]
A new approach is considered to the analysis of the magnetic resonance line shape under slow molecular motions. The essence of the approach consists in calculating the coefficients a_n in the Taylor expansion G(t). A straightforward procedure has been developed for calculating the coefficients a_n for molecular motions described by random Markov processes. (20 refs.)

72656 Different averaging methods in magnetic-resonance theory. L.L.Buishvili, G.V.Kobakhidze, M.G.Menabde (Phys. Inst., Acad. of Sci., Georgian SSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.347-9 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.628-33 (Aug. 1982). [received: May 1983]
The causes of the discrepancy between J. Waugh's mean Hamiltonian theory based on the Magnus expansion, on the one hand, and the averaging method, on the other, are considered. It is shown that the contributions to the line width from the main line and from the satellite are not separated; in a number of cases this is the cause of the discrepancy between the Waugh theory and the experimental data. The general results are illustrated for the case of a two-level system located in a linearly polarized alternating field (the Bloch-Siegert shift). (9 refs.)

76.30 ELECTRON PARAMAGNETIC RESONANCE AND RELAXATION

72657 Simulation of electron spin resonance spectra by fast Fourier transform. J.C.Evans, P.H.Morgan (Dept. of Chem., Univ. Coll. Cardiff, Cardiff, Wales).
J. Magn. Resonance (USA), vol.52, no.3, p.529-31 (May 1983).
Brumby (see ibid., vol.40, p.397 (1980)) has criticized the paper by Evans et al. (see Anal. Chim. Acta. vol.103, p.175 (1978)) on the simulation of EPR spectra and has drawn attention to several points which he believes are unsatisfactory. The 1978 paper describes not only the application of a novel technique of using Fourier transform methods to include time constants and modulation broadening, but also describes their use to simulate spectra from polycrystalline samples and those involving isotopic substitution which has not been done before. The authors purpose is to answer the various points raised by Brumby and to point out a serious error in his paper. (7 refs.)

72658 ESR in the two phases of the magnetic semiconductor $GaCr_4S_8$. P.Huguet, G.Alquie (Lab. de Dispositifs Infrarouge et de Resonance Magnetique, Univ. Pierre et Marie Curie, Paris, France), M.Potel, M.Sergent.
J. Phys. Lett. (France), vol.44, no.10, p.L393-401 (15 May 1983).
Presents new results obtained from ESR experiments in the paramagnetic and magnetically ordered states of both crystallographic phases of the magnetic semiconductor $GaCr_4S_8$. The authors observe a critical behaviour typical of magnetic phase transitions, resulting in a shift and a broadening of the resonance line as well as a distortion of its shape. These features are discussed and related to the presence of magnetization fluctuations. (16 refs.)

72659 Anomalous relaxation in low-dimensional magnets with anisotropic interactions. H.Okamoto, H.Mori (Dept. of Phys., Kyushu Univ., Fukuoka, Japan).
Phys. Lett. A (Netherlands), vol.95A, no.5, p.255-8 (2 May 1983).
Anomalies of the angle-dependent EPR line spectrum and its satellites due to the long-time tails in one- and two-dimensional Heisenberg paramagnets with anisotropy terms are treated in the high-temperature limit by making use of a new mode-coupling theory. A normal lorentzian EPR line spectrum is also expected for some particular combinations of the anisotropic interaction parameters due to the competition between them. (11 refs.)

76.30D Ions and impurities: general

72660 Theoretical study of the dynamic effect caused by low-symmetric distribution of spins on EPR spectra in one-dimensional systems by the method of memory function. Y.Natsume, F.Noda (Dept. of Phys., Chiba Univ., Chiba, Japan), F.Sasagawa, H.Kanazawa.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1427-33 (April 1983).
The fact that the low-symmetric distribution of spins causes the prominent effect on EPR spectra in exchange-interacting one-dimensional paramagnets is verified by a theoretical study on the basis of Mori's memory function method. The characteristic contribution from this effect, which vanishes completely in cases for the high-symmetric distribution of spins, is taken into account in the derivation of spectral function. Obtained spectra depend, in consequence, on the relation between the directions of one-dimensional chain-axis and vibrational field, as well as on that of chain-axis and static field. Characteristic features of the spectra (distortions of lineshape, linewidths and shifts of resonance field) agree well with those of observations in $(CH_3)_4NMnCl_3$ (TMMC). (19 refs.)

72661 EPR spectroscopy of single crystals using a two-circle goniometer. J.R.Morton, K.F.Preston (Div. of Chem., Nat. Res. Council, Ottawa, Ontario, Canada).
J. Magn. Resonance (USA), vol.52, no.3, p.457-74 (May 1983).
The anisotropy of EPR spectra observed in single crystals of various symmetry classes is described. The use of a computer-assisted goniometer to assemble the hyperfine-interaction and g^2 tensors in the crystallographic axis system is explained. (17 refs.)

76.30F Iron group (3d) ions and impurities (Ti-Cu)

72662 Influence of iron concentration and particle size on the ESR linewidth of Al_2O_3:Fe^{3+} powders. R.S.De Biasi, D.C.S.Rodrigues (Secao de Engenhario e Ciencia dos Materiais, Inst. Militar de Engenharia, Rio de Janeiro, Brazil).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.210-12 (May 1983).
The influence of Fe concentration and particle size on ESR linewidth was studied and it was found that the linewidth increased with increasing Fe concentration and decreased with increasing particle size. (2 refs.)

72663 Exchange interactions in bis(diethyldithiocarbamato)copper (II), $Cu(detc)_2$. B.L.Ramakrishna, P.T.Manoharan (Dept. of Chem., Indian Inst. of Technol., Madras, India).
Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.98-102 (6 May 1983).
The exchange coupling constant J in bis (diethyldithiocarbamato)copper (II) has been derived through analysis of the EPR g values and linewidth as a function of orientation, frequency and temperature. The single line in the *ac* plane is due to the averaging of the fine-structure splitting by interdimer exchange for which a lower limit of 0.02 cm^{-1} has been obtained. Analysis of

the spectra of the *bc* plane gives an estimate of 0.008 cm^{-1} for the intersite exchange. (17 refs.)

72664 Effect of quenching rate and annealing on ESR of Cu^{2+} and γ-induced Cd^{+} in low alkali borate glasses. H.Hosono, H.Kawazoe, T.Kanazawa (Dept. of Industrial Chem., Tokyo Metropolitan Univ., Tokyo, Japan).

J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.3-14 (April 1983).

A new ESR hyperfine structure (HFS) of Cu^{2+} was detected in moderately (cooling rate $\approx$3 K/s) and rapidly (10^3-10^5 K/s) quenched borate glasses with Na_2O content smaller than 5 mol.% in addition to the already reported three patterns, spectra I, II and III, for the moderately quenched borate glasses with $5 \lesssim [Na_2O] \lesssim 13$, $20 \lesssim [Na_2O] \lesssim 37$ and $55 \lesssim [Na_2O] \lesssim 75$, respectively. The ESR parameters of this spectrum were much the same as those of II, but a significant difference was observed between thermal stabilities of these spectra. The newly observed spectrum was named spectrum II′. A superposition of spectra II′ and I was seen in low alkali borate glasses ($[Na_2O] \lesssim 5$ mol.%). The relative intensity of II′ to I increased remarkably with increasing quenching rate of the melts and with decreasing alkali content under the same quenching condition. In addition, spectrum II′ was found to relax into I upon thermal annealing of the glasses. Similar changes were observed also in ESR of the γ-induced Cd^{+} with $5s^1$ electronic configuration. A tentative model to account for the spectral changes was proposed on the basis of the characteristics of B-O bonding. (24 refs.)

72665 State of Fe^{3+} ion and Fe^{3+}-F^{-} interaction in calcium fluorosilicate glasses. N.Iwamoto, Y.Makino (Welding Res. Inst., Osaka Univ., Osaka, Japan), S.Kasahara.

J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.113-24 (April 1983).

The state of Fe^{3+} ions and Fe^{3+}-F^{-} interaction in calcium fluorosilicate glasses $xCaF_2.(1-x)CaO.SiO_2$ $(0 \leq x \leq 0.3)$ containing a small amount of iron were investigated by ESR spectroscopy. Two resonances observed near $g=2.0$ and $g=4.3$ were assigned to dipole-dipole interacted Fe^{3+} ions and Fe^{3+} ions in a rhombic crystal field, respectively. The fraction of Fe^{3+} ions in a rhombic crystal field decreased and that of dipole-dipole interacted Fe^{3+} ions in a rhombic crystal field decreased and that of dipole-dipole interacted Fe^{3+} ions increased with increasing Fe_2O_3 content. It was found that the quantity of dipole-dipole interacted Fe^{3+} ions depends on the negative partial charge of fluorine ions and shows a maximum at 10 mol.% CaF_2 $(x=0.2)$. The maximum is attributed to the largest difference between absolute values of the ionic potentials of ferric and fluorine ions which is caused by the smallest negative partial charge of fluorine at 10 mol.% CaF_2. (23 refs.)

72666 Asymmetric lines in field-swept EPR: Cr^{3+} looping transitions in ruby. J.R.Pilbrow, G.R.Sinclair, D.R.Hutton, G.J.Troup (Dept. of Phys., Monash Univ., Clayton, Victoria, Australia).

J. Magn. Resonance (USA), vol.52, no.3, p.386-99 (May 1983).

Electron paramagnetic resonance is almost always observed using fixed-frequency, field-swept spectrometers. At a fixed frequency ν_c the spectral response for transitions between states i and j in field-swept EPR can be written $S(B)=C'|V_{ij}(B)|^2 f(\nu_c - \nu_0(B), \sigma_\nu)$ where C' is an appropriately defined constant at given frequency and temperature, B the applied swept magnetic field, $V_{ij}(B)$ the transition matrix element, f the lineshape function, and σ_ν the frequency domain linewidth. When $S={}^3/_2$, appropriate pairs of non-crossing levels, whose spacings vary nonlinearly with B, give rise to pairs of asymmetric transitions which coalesce at a particular angle from the crystal symmetry axis. These transitions, sometimes referred to as 'looping' transitions, form a convenient basis for a discussion of asymmetric lineshapes in EPR. Experimental spectra showing such transitions have been observed at ~9.5, 4, and 3 GHz for Cr^{3+} ions in ruby single crystals. These are well simulated by theoretical first-derivative field-swept spectra obtained by a point-by-point numerical calculation of $dS(B)/dB$. Frequency-domain Gaussian shape functions f were generally satisfactory, but pseudo-Gaussians with an adjustable exponent $\alpha \leq 2$ were sometimes required. (24 refs.)

72667 ESR of Fe^{3+} centers in $Na_3H(SO_4)_2$ crystals. K.Subba Ramaiah, C.Ramasastry (Dept. of Phys., Indian Inst. of Technol., Madras, India).

Spectrochim. Acta Part A (GB), vol.39A, no.5, p.457-61 (1983).

ESR studies of Fe^{3+} centers in $Na_3H(SO_4)_2$ crystals revealed that the sodium ion vacancies are the charge compensating vacancies. Fe^{3+} ion is trapped at two physically distinct sites and the overall symmetry is not much affected due to the charge compensating vacancies. The data are fitted to the most general spin Hamiltonian by the method of least squares and the spin Hamiltonian parameters are reported. (12 refs.)

72668 Nature of the anisotropy of the spin-spin interaction of Co^{2+} ions in $A_2Zn(ZrF_6)_2.6H_2O$ crystals. V.K.Voronkova, V.E.Petrashen', Yu.V.Yablokov, R.L.Davidovich (Physicotech. Inst., Acad. of Sci., Kazan, USSR).

Sov. Phys.-Solid State (USA), vol.24, no.10, p.1772-3 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3130-3 (Oct. 1982). [received: April 1983]

To discover the factors which determine the anisotropy of the exchange parameters, it is important to trace the trends of the changes in the anisotropy of the spin-spin interaction upon small changes in the symmetry of the ligand field in the nearest neighborhood of the Co^{2+} ion. Such small changes in symmetry are most effectively realized within a single isostructural series of crystals. The authors have studied the ESR spectra of single Co^{2+} ions and Co^{2+}-Co^{2+} pairs in the compounds $A_2Zn_{1-x}, Co_x(ZrF_6)_2.6H_2O$ (x=0.01, 0.1), A=Rb, Cs, NH_4, which are isostructural[3] with $K_2Zn(ZrF_6)_2.6H_2O$, having space group $P2_1/c$, z=2. 76.30K Rare-earth ions and impurities

72669 ESR study on impurity-vacancy aggregation in Eu^{2+} doped and (Eu^{2+}, M^{2+}) doped KCl. K.Kawano, R.Nakata, M.Sumita (Univ. of Electro-Communications, Tokyo, Japan).

J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1402-9 (April 1983).

The aggregates of Eu^{2+} ions doped singly or doubly with M^{2+}(M=Sr, Ca, Cd) in KCl are investigated during the aging process of quenched crystals with ESR at 10, 24 and 34 GHz. New ESR spectra are found corresponding to the aggregation stages in KCl: (Eu^{2+}, Sr^{2+}). At 200 to 500 hours after quenching, the ESR signal due to Eu^{2+} in a cubic field appears with the values of $g=2.002$, $A^{151}=-32.0\times10^{-4}$ cm^{-1} and $b_4{}^0=25.9\times10^{-4}$ cm^{-1}, respectively. The spectrum for the final aggregation stage for 1000 hours is accounted for by assuming M^{2+}-vacancy clusters containing several Eu^{2+}-vacancy dipoles and $g=1.990$ and $b_2{}^0=620\times10^{-4}$ cm^{-1}, $A^{151}=-32.4\times10^{-4}$ cm^{-1} are determined. After further annealing, a broad line with a line width of about 500 oersted appears as the result of the exchange interaction. (21 refs.)

72670 Electron-spin-resonance of some rare-earth ions in cubic intermetallic compounds ($AuCu_3$-structure). T.Gambke, B.Elschner, R.Kremer, M.Schanz (Inst. fur Festkorperphys., Tech. Hochschule Darmstadt, Darmstadt, Germany).

J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.115-24 (April 1983).

The authors report on the ESR of Gd^{3+}, Er^{3+} and Yb^{3+} in MPd_3 (M=Sc, Y, La, Ce, Lu) and $CeRh_3$ intermetallic compounds. X-band (9.3 GHz) measurements were carried out between 0.6 and 40K. Below $T=1.6$K they used their new continuously working He^3 cryostat. The Gd resonance in $ScPd_3$ and YPd_3 shows a weak bottleneck behaviour. In $CePd_3$ the Er resonance was identified as a Γ_7 ground state with a g-value of 6.78. In $ScPd_3$ and YPd_3 they found a Γ_6 ground state for Er possibly affected by a near lying Γ_8 anisotropic quartet and a Γ_7 excited crystal field level for Er^{3+} in $ScPd_3$ and YPd_3. The Yb resonance was to be seen in all MPd_3 and in $CeRh_3$ with Γ_7 ground state. In order to extract the linewidth data, a detailed analysis of the Yb^{3+} resonance spectra has been carried out taking into account both Yb isotopes 171 and 173. Third order corrections for determining the hyperfine constant of Yb 171 became important. The g-shift of all Yb resonance in MPd_3 is the same within the error bars, whereas the linear part of the temperature dependence of linewidth (Korringa slope) scales with the markedly different Pauli susceptibilities. An exponential contribution to the temperature dependence of linewidth in all measured compounds is observed at temperature $T>6$K and is related to direct relaxation of the 4f-momentum via the host phonons (Orbach process). (39 refs.)

72671 Γ_6-ground state resonance in (La, Er)B_6 single crystals. H.Luft, K.Baberschke (Inst. fur Atom- und Festkorperphys., Freie Univ. Berlin, Berlin, Germany), K.Winzer.

Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.186-90 (25 April 1983).

The ESR on cubic (La, Er)B_6 single crystals at three frequencies (4, 9 and 35 GHz) reveals unambiguously a Γ_6 as the Er^{3+} ground state with an excited Γ_8 at 8.5±1K, equivalent to a negative cubic crystal field parameter $A_4\langle r^4\rangle$. The g-shift of $\Delta g=-0.075\pm0.025$ implies a negative effective exchange coupling of $J_{\Delta g}.N(E_F)=-0.075\pm0.025$, whereas the thermal line broadening yields $|J_{\Delta H}.N(E_F)|=0.029\pm0.002$. 72672 Population inversion in the spin states of photoelectrons and the spin-lattice relaxation in narrow-gap semiconductors. V.S.Vikhnin.

Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.34-5 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.452-4 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).

The contribution of band states to spin-lattice relaxation in narrow-gap semiconductors is discussed. It is shown that population inversion in the spin states of conduction electrons and the maser effect in graded-gap semiconductors are possible. (1 ref.)

76.30R Free radicals

72673 ESR effects of singlet-triplet mixing in radical pairs. Determination of the individual g tensors and the exchange coupling constant from spectral shifts due to off-diagonal Zeeman terms. J.R.Byberg, N.Bjerre (Dept. of Chem., Aarhus Univ., Aarhus, Denmark), A.Lund, P.-O.Samskog.

J. Chem. Phys. (USA), vol.78, no.9, p.5413-19 (1 May 1983).

ESR spectra of exchange-coupled radical pairs exhibit shifts in the fine structure splitting proportional to the square of the microwave frequency ν_0 and shifts in the hyperfine splittings proportional to ν_0, provided the g tensors of the members of the pairs are nonequivalent. These shifts stem from electronic Zeeman terms in the full spin Hamiltonian of the pairs, which tend to mix the singlet and triplet electron spin states. Expressions for the shifts are derived from a second order perturbation calculation based on the conventional triplet description. The results are employed to obtain the individual g tensors and the exchange coupling constant for a radical pair formed by X irradiation at 26K of pentaerythritol crystal. (6 refs.)

76.40 DIAMAGNETIC AND CYCLOTRON RESONANCES

72674 Electromagnetic excitations in noble metals. V.Ya.Demikhovskii, S.S.Savinskii (Fiftieth Anniversary of the Soviet Union Udmurt State Univ., Izhevsk, USSR).

Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.433-40 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*

Numerical calculations are made of the cyclotron masses, average velocities of carriers, and Fourier components of these velocities on cyclotron orbits in noble metals. In these calculations the Fermi surface is specified analytically and five fitting parameters (deduced from the de Haas-van Alfven effect) are employed. Data are given on the spectrum and damping of helicons and Ag and Cu for the case when $\mathbf{H}\|C_4$. The local conductivity is calculated numerically for high frequencies in the range $\omega\sim\omega_c$. It is shown that near the first cyclotron resonance associated with the 4R hole orbits there is a cyclotron wave with $\mathbf{q}\perp\mathbf{H}$ and an 'anisotron' wave with $\mathbf{q}\|\mathbf{H}$. The anisotron spectra are found in the long-wavelength limit for silver and copper in the $\mathbf{H}\|C_4$ case. (8 refs.) *A.T.*

72675 Cyclotron resonance of a polaron. M.Saitoh (Cavendish Lab., Univ. of Cambridge, Cambridge, England).

J. Phys. A (GB), vol.16, no.8, p.1795-808 (1 June 1983).

The theory of the mass shift and the linewidth of the cyclotron resonance of a polaron is given. The lineshape function which was obtained earlier by the author on the basis of the path-integral method with an optimised model is utilised. This formula has the particular advantage of being applicable on a unified footing to electron-photon interactions of any strength, elastic or inelastic. Applications are made to the Frohlich polaron system and explicit analytical expressions are obtained for the first time for some limiting cases of interest. (29 refs.)

72676 Critique of the theories of cyclotron resonance lineshape. Sang Don Choi, Ok Hee Chung (Dept. of Phys., Kyungpook Nat. Univ., Taegu, South Korea).
Solid State Commun. (USA), vol.46, no.4, p.355-7 (April 1983).
Argyres-Sigel's critique (1974) of the theories of cyclotron resonance lineshape obtained by Kawabata (1967)and by Łodder and Fujita (1968) is reviewed. All the higher order terms in the expansion of the lineshape functions are proved to be finite at the resonance peaks as well as in the wings of the absorption lines, implying that the critique is unreasonable. (9 refs.)

72677 Cyclotron resonance in a degenerate plasma of a semiconductor with a superlattice. V.A.Lykakh, A.P.Tetervov (Inst. of Semiconductor Phys., Acad. of Sci., Vilnius, Lithuanian SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1358-60 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2105-9 (Dec. 1982). [received: May 1983]
An analysis is made of the characteristics of cyclotron absorption in a degenerate plasma of a semiconductor with a one-dimensional superlattice, subjected to crossed static fields. It is shown that characteristics of the electron distribution function and the nonparabolicity of the electron spectrum have the effect that the cyclotron resonance can be observed only in a certain range of frequencies of an external electromagnetic field. (5 refs.)

(see also 75.30D Spin waves)

72678 Spin wave resonance in ferromagnets with dislocations forming a periodic layered structure. W.Schmidt (Inst. of Molecular Phys., Polish Acad. of Sci., Poznan, Poland).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.497-506 (April 1983).
The influence of dislocations forming a periodic layered structure on the ferromagnetic resonance has been studied. A dislocation distribution function within a layer has been taken as constant while signs of dislocations in neighbouring layers are opposite. Expressions for frequencies and intensities for both quasiuniform and space modes have been found. The gap between the quasiuniform and space modes is considerable. The space mode shows up in a resonance as a separate peak or, in the case of a very wide line, makes the quasi-uniform mode peak asymmetric. (10 refs.)

72679 Approximate theory of FMR and AR in weakly conducting ferromagnetic bulk metals. D.Fraitova (Inst. of Phys., Czechoslovak Acad. Sci., Praha, Czechoslovakia).
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.5, p.574-84 (1983).
The analytical expressions for the dispersion relations, the surface impedance, the line widths and the shifts of the resonance and antiresonance points are presented for the case of the ferromagnetic resonance (FMR) and the antiresonance (AR) in the parallel configuration and in the linear approximation of electrical conductivity. Further on, the amplitudes of the HF components of the magnetic field, of the magnetization, and the factors of ellipticity for three pairs of the waves propagating in the ferromagnetic bulk metal are derived in the FMR and AR regions. For the case of the FMR region the theory is valid only for the case of $\epsilon^2 \ll \Omega^2 L^2$, i.e. for materials with a low electrical conductivity, a small exchange stiffness constant, a large L.L. damping parameter at high frequencies, respectively. (16 refs.)

72680 Ferromagnetic resonance in holmium-yttrium iron garnets in the Ising model. R.Z.Levitin, A.I.Popov, V.V.Snegirev.
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1777-8 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3138-40 (Oct. 1982). [received: April 1983]
The authors show that the model of Ising-like ordering enables one to describe the features of the ferromagnetic resonance of holmium-yttrium iron garnets $Ho_xY_{3-x}Fe_5O_{12}$. (10 refs.)

76.60 NUCLEAR MAGNETIC RESONANCE AND RELAXATION

72681 High-temperature investigations of NMR of ^{27}Al in dilute aluminium-zinc alloys. V.F.Kruglov, S.V.Verkhovskii, G.V.Kleshchev (Pedagogical Inst., Chelyabinsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.617-19 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An investigation was made of the integrated intensity of the NMR signal of ^{27}Al in alloys of aluminium containing 1.05 and 2.14 at.% Zn. The investigation was carried out at temperatures from the room value to 673K. The results were used to draw some conclusions on the thermal averaging of the electric field gradients and on the distribution of Al nuclei around Zn nuclei. (9 refs.) *A.T.*

72682 Parameters of Cu nuclear spin Hamiltonian in mixed crystals $(CH_3NH_3)_2Cu(Cl_{1-x}Br_x)_4$. H.Kubo (Dept. of Electronics, Kyushu Univ., Fukuoka, Japan), Y.Suzuki, M.Tanimoto, N.Uryu.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1373-81 (April 1983).
NMR measurements of Cu nuclei are carried out in the ferromagnetic region of these mixed crystals to clarify the dependences of the hyperfine field, H_{hf}, and the quadrupole frequency, ν_Q, on the surrounding ligand ions. Since the Cu^{2+} ground state is given by $d(x^2-y^2)$, the obtainedvalues of H_{hf} and ν_Q are due to the number, n, of BR$^-$ ions in the four ligands on the x- and y-axes and are fitted by the experimental formula, $H_{h}{}^{\mu}{}_{f}=H_{h}{}^{\mu}{}_{f}(0)+k_{h}{}^{\mu}{}_{f}n$ $(\mu{:}x,y,z)$ and $\nu_Q=\nu_Q(0)+k_Q n$, where k is the proportional constant. The differences between the hyperfine field along the x-axis and the y-axis are observed and are interpreted by the deviation from the tetragonal crystalline field. (17 refs.)

72683 Distribution of Cl$^-$ and Br$^-$ ions in mixed crystals $(CH_3NH_3)_2Cu(Cl_{1-x}Br_x)_4$. Y.Suzuki (Dept. of Electronics, Fukuoka Inst. of Technol., Fukuoka, Japan), H.Kubo.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1420-6 (April 1983).
NMR measurements of Cu and Cl nuclei are carried out at 1.75K to clarify the distribution of Cl$^-$ and Br$^-$ ions in the slowly grown mixed crystals $(CH_3NH_3)_2Cu(Cl_{1-x}Br_x)_4$ from an aqueous solution. The analysis of the Cu NMR spectra reveals that the Cl$^-$ and Br$^-$ ions do not distribute at random. By comparing the NMR intensities of Cl nuclei on the c-axis with those in the c-plane, it is concluded that most of Cl$^-$ ions preferentially occupy the positions in the c-plane.

72684 The ^{55}Mn and ^{57}Fe NMR study of FeCrMn alloys. H.Enokiya, M.Kawakami, R.Tanaka (Dept. of Phys., Kagoshima Univ., Kagoshima, Japan), T.Hihara.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1434-8 (April 1983).
The nuclear magnetic resonance (NMR) study has been made for the ^{55}Mn and ^{57}Fe nuclei in disordered ferromagnetic alloys $(Fe_{1-x}Cr_x)_{0.99}Mn_{0.01}$ $(x \leq 0.3)$ by the spin echo method in zero external magnetic field at 1.7K. The frequency corresponding to the centre of gravity of the ^{55}Mn NMR spectrum increases from 239.9 MHz at $x=0$ up to a maximum value of 267 ± 5 MHz at $x=0.20$ with increasing x and then decreases down to 236.4 MHz at $x=0.30$. The deduced value of the Mn magnetic moment increases monotonically from 0.72 μ_B at $x=0$ with increasing x, passes a maximum value of 1.33 μ_B at $x=0.20$ and then decreases to 1.2 μ_B at $x=0.3?$. This variation of the Mn moment with x is correlated with that of the Cr magnetic moment, and it is suggested that the moment of the Mn impurity is more localised in alloys with a higher Cr content. The ^{57}Fe NMR spectrum is also discussed.

72685 Multipole NMR. III. Multiplet spin theory. B.C.Sanctuary (Dept. of Chem., Univ. of York, Heslington, England).
Mol. Phys. (GB), vol.48, no.6, p.1155-76 (20 April 1983).
In selective multiquantum NMR specific transitions in the $(2I+1)$ manifold of levels are excited. In order to treat this problem the concept of multiplet spin I_M is introduced which takes all groups of closest $(2I_M+1)$ multiplets out of the $(2I+1)$ levels. The theory of multiplet spin is developed and related to the fictitious spin-$^1/_2$ formalism and the multipole approach. (26 refs.)

72686 NMR of ^{27}Al in paramagnetic single-crystal $DyAl_2$. Y.B.Barash, J.Barak (Soreq Nuclear Res. Centre, Yavne, Israel), A.Grayevsky.
Phys. Lett. A (Netherlands), vol.95A, no.5, p.252-4 (2 May 1983).
NMR of ^{27}Al was observed in a spherical single crystal of $DyAl_2$ in the paramagnetic state. The well split quadrupole spectrum yielded a quadrupole frequency $\nu_Q=561$ kHz and hyperfine constant $H_{hf}{}^{P}=-3.17$ kOe/n_B. The anisotropy on the spectrum is well explained by the dipolar interaction. (6 refs.)

72687 Nuclear magnetic resonance studies on sequence distributions in vinyl alcohol-vinyl acetate copolymers. S.Toppet (Dept. of Chem., Katholieke Univ. Leuven, Leuven, Belgium), P.J.Lemstra, G.Van der Velden.
Polymer (GB), vol.24, no.5, p.507-12 (May 1983).
The microstructure of vinyl alcohol-vinyl acetate copolymers was studied using both ^{13}C NMR and ^{1}H NMR techniques. The sequence lengths of vinyl acetate units calculated respectively from the compositional dyads, from the methylene absorptions and from the triple carbonyl absorptions in the ^{13}C NMR spectrum were not identical, and moreover the dyad-triad relationship showed a large discrepancy. ^{1}H and ^{13}C NMR spectra of a 5 mol.% reacetylated random sample, containing mainly isolated acetate units, indicate that configurational splitting complicates the assignment of the triple carbonyl absorption, which originally was interpreted as a compositional triad. After correcting for tacticities the results could be brought in line and the C=O resonances proved to be useful in obtaining information on the percentage of isolated vinyl acetate units and the sequence length $n_{2+}{}^{A}$ (the average length of vinyl acetate units ≥ 2). (30 refs.)

72688 Influence of rare earth subsystem on NMR gain in $ErFeO_3$. I.M.Vitebskii, A.S.Karnachev, E.E.Solov'ev (Physicotech. Inst., Acad. of Sci., Donetsk, Ukrainian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1757-9 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3106-9 (Oct. 1982). [received: April 1983]
An experimental and theoretical study is made of the temperature dependence of the NMR gain in erbium orthoferrite at temperatures in the spin-reorientation region for different orientations of the exciting field with respect to the crystallographic axes. (4 refs.)

72689 Dynamic NMR frequency shift in the inverted state. V.I.Tsifrinovich (L.V. Kirenskii Inst. of Phys., Acad. of Sci., Krasnoyarsk, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.399-400 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.715-17 (Aug. 1982). [received: May 1983]
The motion of the nuclear magnetization in the inverted state under the conditions of the dynamic NMR frequency shift is investigated. The conditions under which the NMR line has different shapes in the equilibrium and inverted states are found. It is shown that the line width changes considerably during the quasistationary transient process. (5 refs.)

76.60C Chemical and Knight shifts

72690 ^{13}C NMR chemical shift tensors of metal carbonyls. J.W.Gleeson, R.W.Vaughan (Div. of Chem. & Chemical Engng., California Inst. of Technol., Pasadena, CA, USA).
J. Chem. Phys. (USA), vol.78, no.9, p.5384-92 (1 May 1983).
The principal components of the ^{13}C NMR chemical shift tensors of metal carbonyls containing between one and six metal atoms were determined from their powder patterns. The tensors of terminally bound CO groups are highly anisotropic (380±60 ppm) and nearly axially symmetric. The tensors of bridging CO groups are much less anisotropic, due to significant asymmetry in the electron orbitals about the C-O internuclear axis. The tensors vary only slightly for different transition metals. There is no intramolecular rearrangement of the metal carbonyls in the solid state at frequencies greater than 10 kHz, except in $Fe_3(CO)_{12}$. (58 refs.)

72691 Simulation of quadrupole disturbed NMR field spectra by using the exact solution of the Hamiltonian: application to zinc. J.Abart, E.Palangie, W.Socher, J.Voitlander (Inst. fur Phys. Chem., Univ. Munchen, Munchen, Germany).
J. Chem. Phys. (USA), vol.78, no.9, p.5468-73 (1 May 1983).
The NMR signals of ^{67}Zn in polycrystalline zinc metal have been observed at frequencies between 8.8 and 13 MHz. Because of the large quadrupole interaction, the spectra have been recorded by sweeping the magnetic field. In order to evaluate the spectra with high accuracy, the authors have developed a variational method which is based on the exact solution of the NMR-Hamiltonian, for calculating the transition fields, the appropriate transition intensities and from those field spectra. From the comparison between the simulated and the experimental spectra of Zn, the authors evaluated a quadrupole coupling constant e^2qQ/h of 12.73 (4) MHz, an isotropic Knight shift K_{iso} of 0.15 (3)% and an axial one K_{ax} of 0.03 (3)%. The results are discussed in comparison with already known data. (22 refs.)

Nuclear magnetic resonance and relaxation in itinerant electron ferromagnet Ni_3Al ....See Entry 72692

76.60E Relaxation effects

72692 Nuclear magnetic resonance and relaxation in itinerant electron ferromagnet Ni_3Al. T.Umemura, Y.Masuda (Dept. of Phys., Nagoya Univ., Nagoya, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1439-45 (April 1983).
The nuclear magnetic relaxation rate of ^{27}Al in an itinerant electron ferromagnet Ni_3Al has been measured. The measurements were performed in the external fields from 1.0 to 50.0 kOe in both ordered and paramagnetic states. The temperature dependence of the Knight shift and susceptibility gives the hyperfine field arising from the Ni 3d-spin of $H_{hf}^{Al}(d)=-7.60$ kOe per Bohr magneton per Ni atom. The experimental results of the external field dependence of $(T_1T)^{-1}$ were reasonably well explained by using the self-consistent renormalisation (SCR) theory which takes account of the effect of spin fluctuations. (12 refs.)

72693 NMR study of solid perfluorocyclobutane. E.Szczesniak, J.R.Brookeman (Dept. of Phys., Univ. of Florida, Gainesville, FL, USA).
Mol. Phys. (GB), vol.48, no.6, p.1221-8 (20 April 1983).
Spin-lattice relaxation times and linewidth measurements for fluorine nuclei in solid perfluorocyclobutane are presented. The results are discussed in terms of D_{2d} molecular species performing fast internal motion. The relaxation measurements corroborate the existence of four solid-solid phase transitions and give some insight into their nature. The activation energies for molecular reorientation and self-diffusion processes are found to be 28.0 and 32.2 kJ mol.$^{-1}$, respectively. (20 refs.)

72694 Molecular reorientations of 1-bromo- and 1-iodo-adamantanes—^1H NMR relaxation study. J.Virlet, L.Quiroga, B.Boucher (Dept. de Phys.-Chimie, CENS, Gif-sur-Yvette, France), J.P.Amoureux, M.Castelain.
Mol. Phys. (GB), vol.48, no.6, p.1289-303 (20 April 1983).
Second moments and spin-lattice relaxation times, T_1 and $T_{1\rho}$, have been measured from 100K to 400K for the protons in powdered 1-bromo and 1-iodo-adamantanes. Analysis of these data have shown that the reorientations are uniaxial in the low temperature phases. In the high temperature disordered phase of bromo-adamantane, the reorientation is endospherical and a slow molecular translational motion also exists. In the high temperature disordered phase of iodo-adamantane the reorientation is 12-fold uniaxial, in agreement with the incoherent quasi-elastic neutron scattering (IQNS) experiments. All the results correspond to the crystallographic structures deduced from X-ray scattering. (20 refs.)

72695 T_1 as a function of Larmor frequency in solid CH_4 at 4.2K: an experiment on recent theories. E.Agostinelli, P.Calvani (Dipartimento di Fisica, Univ. di Roma I, Rome, Italy).
Phys. Lett. A (Netherlands), vol.95A, no.2, p.118-20 (18 April 1983).
The spin-lattice relaxation time T_1 has been measured in partially converted samples at NMR frequencies ranging from 5 to 55 MHz. Results allow to check in detail the existing models for relaxation in solid CH_4. (10 refs.)

76.60G Quadrupole resonance

72696 NQR study of the molecular motions of the ClO_3^- ion in chlorates. J.Kasprzak, J.Pietrzak (Inst. of Phys., A. Mickiewicz Univ., Poznan, Poland).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.461-8 (April 1983).
^{35}Cl NQR frequency and spin-lattice relaxation time measurements for polycrystalline samples of sodium, barium and silver chlorates are reported. The following motional processes have been identified to be responsible for the electric field gradient (EFG) averaging and spin-lattice relaxation: anharmonic torsional motions in the low temperature range, hindered rotation of the ClO_3^- ion in the high temperature range and diffusion of water molecules in the case of barium chlorate. From data analysis, the activation energies for the above types of motions are determined. In silver chlorate a phase transition was observed at 415K. (18 refs.)

76.60L Spin echoes

72697 NMR spin echoes and quadrupole effects in nickel single crystals. J.Bunke, H.Bromer (Inst. a fur Phys., Abteilung fur Angewandte Kern- & Neutronenphys., Techn. Univ. Carolo-Wilhelmina, Braunschweig, Germany).
Hyperfine Interactions (Netherlands), vol.14, no.1, p.89-95 (April 1983).
NMR spin echo measurements of naturally abundant ^{61}Ni have been performed with Neel-type nickel single crystals at 4.2K. The NMR excitation condition could properly be chosen in order to get signals either from nuclei situated within magnetic domains or within domain walls. In both cases a quadrupole splitting of the NMR line could be observed. By applying an external magnetic field, the direction of the domain magnetization could be varied with respect to the FCC crystal lattice. From the variation of the quadrupole splitting with the crystallographic direction, the tensor of the electric field gradient (EFG) has been derived. The quadrupole splittings and the corresponding field gradients in the principal axis system of the EFG are: $\Delta\nu_{Q\langle 111\rangle}=13\pm1$ kHz, $\Delta\nu_{Q\langle 1\bar{1}0\rangle}=9\pm1$ kHz, $\Delta\nu_{Q\langle 11\bar{2}\rangle}=4\pm1$ kHz, $V_{\langle 111\rangle}=(6.6\pm0.5)\times10^{18}$ V/m^2, $V_{\langle 1\bar{1}0\rangle}=(4.6\pm0.5)\times10^{18}$ V/m^2, $V_{\langle 11\bar{2}(}=(2.0\pm0.5)\times10^{18}$V/m^2. (11 refs.)

76.70 MAGNETIC DOUBLE RESONANCES AND CROSS EFFECTS

72698 Spin effects in p^+-i-n^+ a-Si:H cells; photovoltaic detected magnetic resonance (PDMR). K.P.Homewood, B.C.Cavenett (Dept. of Phys., Univ. of Hull, Hull, England), W.E.Spear, P.G.LeComber.
J. Phys. C (GB), vol.16, no.13, p.L427-31 (10 May 1983).
This paper reports spin-dependent photovoltaic effects in p^+-i-n^+ a-Si:H cells. The preliminary results are important for two reasons. Firstly, the method of photovoltaic detected magnetic resonance (PDMR) complements the well known optically detected magnetic resonance (ODMR) technique as a means for investigating recombination processes in these devices, particularly since it is sensitive to all radiative and non-radiative processes. Secondly, the remarkable sensitivity of PDMR even up to room temperature suggests that the method is suitable for routine assessment of both amorphous and crystalline photovoltaic junctions and barrier devices. (14 refs.)

76.70E Dynamical nuclear polarization

72699 Electron-nuclear interactions in semiconductors during optical pumping. N.T.Bagraev (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.36-42 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.455-62 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Conditions for optical polarization of nuclei in semiconductors during the hyperfine interaction with electrons trapped by impurity centers are examined. Optical polarization of nuclei in silicon doped with different impurities is investigated. Optimum conditions for producing the maximum polarization of lattice nuclei are determined. (16 refs.)

72700 Optical polarization of nuclear angular momenta in amorphous Si-Dy. N.T.Bagraev, L.S.Vlasenko, M.M.Mezdrogina (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.43-5 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.463-5 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Optical polarization of nuclei in the amorphous semiconducting alloy Si-Dy has been demonstrated. It is interpreted as being due to magnetic-ordering processes which result in the formation of ferrons, i.e. regions with local magnetic order. Nuclear polarization is found to be due to hyperfine interactions with three ferrons and with ferrons localized on broken bonds in the amorphous semiconducting alloy. (6 refs.)

72701 Application of optical polarization of nuclear moments and of NMR to the study of the physical properties of doped semiconducting materials. N.T.Bagraev, L.S.Vlasenko (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.46-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.466-8 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Optical polarization of lattice nuclei in crystals is used to investigate the decay of solid solutions of gold in dislocation-free silicon and in silicon containing different dislocation densities in the range 10^2-10^5 cm^{-2}. (6 refs.)

72702 Excited triplet states and optical polarization of nuclear magnetic moments in semiconductors. L.S.Vlasenko (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.49-54 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.469-75 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Optical polarization of nuclei was investigated in silicon containing crystal defects such as radiation defects, thermal defects, and dislocations. (no refs.)

72703 Optical polarization of nuclei and ESR in irradiation silicon. N.T.Bagraev, L.S.Vlasenko, V.M.Rozhkov (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.55-7 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.476-9 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
A study is reported of optical polarization of lattice nuclei in silicon bombarded with electrons. It was found that the change in the size of the ESR signals due to Si-Si centers, which is observed in irradiated silicon under illumination, is correlated with a change in the optical polarization of ^{29}Si during the annealing of radiation defects. (3 refs.)

72704 Optical polarization of nuclei in the presence of deep impurity levels. L.L.Buishvili, N.P.Giorgadze, A.I.Tugushi (Tbilisi State Univ., Tbilisi, Georgian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.58-9 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.480-1 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
An analysis is given of possible mechanisms for the dynamic polarization of nuclei as a result of interaction with optically aligned electron spins of deep impurity centers. (6 refs.)

72705 Optical alignment of the bound electron-nuclear spin system of a semiconductor. R.I.Dzhioev, V.G.Fleisher (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.65-9 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.487-91 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
The optical alignment of the spins in a semiconductor can be accompanied by the appearance of internal feedback in the electron-nuclear spin system (ENSS). The importance of this effect increases with increasing time T_S during which the spin alignment of the electrons persists, and with increasing value of the ratio H_N/H of the effective field due to the nuclei to the external field. Under these conditions, the degree of circular polarization of the luminescence emitted by the semiconductor is a complicated function of small changes in the external magnetic field. Experimental results of this effect are presented, and it is concluded that optical alignment of electrons and nuclei in the presence of a strong interaction between them leads to new optical and magnetic phenomena which can be observed in weak magnetic fields, which is unusual in magnetooptics of semiconductors. (9 refs.)

72706 Optical cooling of the nuclear spin system of a semiconductor in conjunction with adiabatic demagnetization. V.K.Kalevich, V.D.Kul'kov, V.G.Fleisher (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.70-2 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.492-4 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
An analysis is given of the cooling of the nuclear spin system of a semiconductor which includes optical cooling by σ-light in a longitudinal magnetic field, followed by adiabatic demagnetization. (4 refs.)

72707 Effect of the field due to optically aligned electrons in a semiconductor on the polarization of nuclei in an inclined magnetic field. B.P.Zakharchenya, V.K.Kalevich, V.D.Kul'kov, V.G.Fleisher (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.73-5 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.495-7 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Optical alignment of conduction electrons in GaAs type semiconductors is accompanied by the polarization of the crystal nuclei as a result of the hyperfine interaction. In its turn, the effective magnetic field H_N due to the polarized nuclei acts on the average spin $\langle S\rangle$ of the aligned electrons. In practice, the degree of alignment of the electrons is determined by measuring the circular polarization $\rho = \langle S\rangle$ of the emitted luminescence. The presence of the nuclear field gives rise to a complicated dependence of ρ on the magnetic field. In a strong inclined magnetic field H, the effect of the nuclear field H_N gives rise to the appearance of an additional maximum on the ρ(H) curve for fields close to $H = H_N$. The direction of the field H_N depends on the sign of the g-factor of the conduction electrons. The authors show experimentally and theoretically that, in an inclined field, the $\rho(H)$ curve exhibits not only the above additional maximum but also a further maximum (which appears in a relatively weak field) which is connected with the compensation of the electron field H_e by the longitudinal component of the external field. (6 refs.)

72708 Resonance cooling of the nuclear spin system of a semiconductor with optically aligned electrons: experimental part. V.K.Kalevich, V.D.Kul'kov, V.G.Fleisher (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.498-501 to 76-9 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Optical cooling of the nuclear spin-system of a semiconductor when the conduction electrons are pumped by modulated circularly-polarized radiation in a perpendicular magnetic field whose strength is close to the resonance field for the lattice isotope, leads to the appearance of an effective magnetic nuclear field that is collinear with the external field. The direction of the nuclear field due to the individual isotopes corresponds to the negative sign of the g-factor g^* of the conduction electrons in GaAs, and to the positive sign in $Ga_{0.5}In_{0.5}P$. (7 refs.)

72709 Resonance cooling of the nuclear spin system in a semiconductor with optically aligned electrons: theoretical part. I.A.Merkulov, M.N.Tkachuk (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.80-2 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.502-4 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
A theoretical analysis is given of the cooling of the nuclear spin system in the lattice of a semiconductor, due to the hyperfine interaction with polarized electrons. Equations are derived for the temperatures of the Zeeman and the dipole-dipole reservoir. They constitute a generalization of the Provotorov equations dipole reservoir. They constitute a generalization of the Provotorov equations to the case where there is an interaction between the nuclei and the polarized electrons. (3 refs.)

72710 Experimental setup for enhanced ^{13}C NMR spectroscopy in solids using dynamic nuclear polarization. R.A.Wind, F.E.Anthonio, M.J.Duijvestijn, J.Smidt, J.Trommel, G.M.C.De Vette (Dept. of Appl. Phys., Delft Univ. of Technol., Delft, Netherlands).
J. Magn. Resonance (USA), vol.52, no.3, p.424-34 (May 1983).
If a solid contains free electrons the dynamic nuclear polarization (DNP) technique can be applied to enhance the ^{13}C signal by one or two orders of magnitude. The method demands irradiation near the electron Larmor frequency. The microwave part of the experimental setup is described as well as two probes in which DNP can be combined with ^{13}C FID or ^{13}C-^1H cross polarization experiments. In one of the probes magic-angle spinning can also be performed. The magnetic field strength used is 1.4T. Measurements are shown of enhanced ^{13} FID and CP spectra of a low volatile bituminous coal and of polystyrene doped with a stable radical. (19 refs.)

72711 Resonant cooling of the spin system of a superconductor lattice nuclei following optical orientation of the electrons [for superconductor read semiconductor]. I.A.Merkulov, M.N.Tkachuk (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.342-6 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.62-7 (Aug. 1982). [received: May 1983]
Cooling of the spin system of lattice nuclei as a result of hyperfine interaction with polarized electrons is considered when the mean electron spin (S) and the external alternating magnetic field (H_1) oscillate at a frequency close to that of the nuclear magnetic resonance. The equations obtained for the Zeeman and dipole-dipole reservoir temperatures are an extension of the Provotorov equations to the case of interaction between nuclei and polarized electrons. Solutions of the equations are presented for strong and weak magnetic fields. It is shown that the degree of cooling of the nuclear spin system has a resonant dependence on the modulation frequency of S and of H_1. In the case of an extremely weak alternating field the dependence is determined by the correlators of the total spin of the lattice nuclei. The solution for a saturating field H_1 does not depend on the form of the spin correlators. (8 refs.)

72712 Dynamic polarization and NMR of nuclei in the immediate vicinity of paramagnetic impurity centers. M.D.Zviadadze, B.D.Mikaberidze (Phys. Inst., Acad. of Sci., Georgian SSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.441-7 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.787-98 (Aug. 1982). [received: May 1983]
The authors investigate the dynamic polarization mechanisms and calculate the polarization amplification factors and the absorption signals of the NMR 04 nuclei in the immediate vicinity of paramagnetic impurity centers in solid dielectrics under conditions of pulsed and steady saturation of allowed and forbidden EPR transitions of the impurity, with account taken of the electron dipole reservoir. In contrast to the impurity nuclei proper and the remote nuclei of the host lattice, the nearby nuclei are polarized even under pulsed saturation of allowed transitions. It is known that the preliminary polarization of the nearby nuclei by microwave pumping can increase the sensitivity of NMR-signal measurements by two or three orders of magnitude. (24 refs.)

72713 New possibility for EPR studies by laser polarimetry. E.B.Aleksandrov, V.S.Zapasskii.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.6-10 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.423-8 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
The authors investigate the possibilities of optical EPR methods that rely on the use of laser sources. Magnetic resonance spectra are recorded in the noise spectra of the Faraday rotation of a laser beam induced by various paramagnetic crystals. It is found that, without complicating the optical EPR detection, magnetization noise turns out to be of interest in itself and provides a completely new approach to the study of paramagnetism. The spectrum of the magnetization fluctuations contains the same information as the EPR spectrum, but, in contrast to the EPR spectrum which is proportional to the magnetic polarization of the medium and for which the resonance must be induced by a variable magnetic field, the magnetization is found to fluctuate even when the average macroscopic magnetization is zero or even when the variable external field is zero. This presents one with a unique possibility of being able to investigate the relaxation times as functions of the field H and temperature T without imposing the restrictions on these two variables that are necessary in conventional EPR techniques in which the signal strength depends on the ratio H/T. (12 refs.)

72714 Optical detection of EPR using the luminescence emitted by crystal defects. P.G.Baranov (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.15-21 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.433-9 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Recent work using optical detection of EPR in crystal defects is reviewed. The review covers papers in which recombinational tunnelling afterglow has been used to detect EPR in electron and hole centers in crystals, and summarizes the results of studies of the spatial distribution of wave functions of unpaired electrons in doublet and triplet relaxed excited states. (18 refs.)

72715 Giant spin splitting of exciton states and optically detected magnetic resonance in A^2B^6 crystals containing magnetic impurities. S.M.Ryabchenko (Phys. Inst., Acad. of Sci., Ukrainian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.22-7 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.440-5 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
A review is given of recent work on giant spin splitting of exciton states in magnetically mixed semiconductors of the form $A^2{}_xMe_xB^6(A^2B^6{:}Me$, where Me-3d metal), which appears as a result of the exchange interactions between carriers and localized magnetic moments during spin polarization of the latter by an external magnetic field. A model of the phenomenon is described and its various manifestations in magnetooptics are discussed. (24 refs.)

76.80 MÖSSBAUER EFFECT; OTHER GAMMA-RAY SPECTROSCOPY

72716 Influence of the distribution of carbon atoms on the quadrupole interaction in Fe-Ni-C austenite. V.G.Gavrilyuk, V.M.Nadutov (Inst. of Metal Phys., Acad. of Sci., Kiev, Ukrainian SSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.520-7 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An analysis was made of the various configurations of iron and carbon atoms at the nearest interstices in the f.c.c. lattice on the magnitude and sign of the electric field gradient (EFG) and, consequently, on the quadrupole interaction of the iron atoms. In the case of iron atoms with one or two carbons at the nearest octahedral interstices the EFGs were identical in magnitude and opposite in sign. In the case of the dumbbell configuration the EFGs were twice as high. The results of a Mossbauer effect study indicated the existence, in the investigated austenite, of a pair of carbon atoms at interstices next to resonating iron nuclei. (19 refs.) *A.T.*

72717 Investigation of technical-grade beryllium by the Mossbauer effect method. Yu.P.Khimich, G.N.Belozerskii, V.N.Gittsovich, S.V.Lyubarskii, S.B.Tomilov, G.V.Bel'chenko (A.A. Zhdanov State Univ., Leningrad, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.610-12 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the redistribution of carbon atoms, and of the formation and dissolution of excess phases containing iron as a result of heat treatments applied to hot-pressed beryllium prepared by the ceramic method. The annealing temperature (450-1000°C) affected not only the relative intensities of the components of the Mossbauer spectra but also other parameters. The results obtained of a study of the rolling texture indicated that the Mossbauer effect in ^{57}Fe nuclei provided an effective method for investigating the structure and phase of beryllium. (10 refs.) *A.T.*

72718 Measurements of the hyperfine magnetic fields at Ta and Fe in the Laves compound $(Zr_xHf_{1-x})Fe_2$ for $0 \leq x \leq 1$. Z.Z.Akselrod, M.Budzynski, T.Khazratov, B.A.Komissarova, L.N.Kryukova, S.I.Reiman, G.K.Ryasny, A.A.Sorokin (Inst. of Nuclear Phys., Moscow State Univ., Moscow, USSR).
Hyperfine Interactions (Netherlands), vol.14, no.1, p.7-19 (April 1983).
The hyperfine magnetic fields at ^{181}Ta and ^{57}Fe in the ferromagnetic Laves intermetallic compounds $(Zr_xHf_{1-x})Fe_2$ $(0 \leq x \leq 1)$ have been measured by the methods of TDPAC and Mossbauer effect, respectively, and shown to be practically independent of x at $x \geq 0.4$. An average value $B_{hf}(Ta) = -6.52$ T at 300K was obtained for samples with $x \geq 0.4$, and -14.2 T for pure $HfFe_2$ in the hexagonal C14 modification. For $0 < x < 0.4$, a superposition of both field components was observed. A deviation of the temperature dependences of $B_{hf}(Ta)$ in $(Zr_{0.9}Hf_{0.1})Fe_2$ from that for $B_{hf}(Fe)$ and the bulk magnetization was confirmed, studied in detail, and shown to exist for all $x \geq 0.4$. The temperature dependence of $B_{hf}(Ta)$ in $HfFe_2$ was close to that of $B_{hf}(Fe)$. (18 refs.)

72719 Analytical solution for the ^{57}Fe Mossbauer spectra for octahedral cage hopping and correlated electric field gradient fluctuations. F.J.Litterst, V.D.Gorobchenko, G.M.Kalvius (Phys. Dept. Techn. Univ. Munchen, Munchen, Germany).
Hyperfine Interactions (Netherlands), vol.14, no.1, p.21-35 (April 1983).
The authors derive an analytical solution for the Mossbauer relaxation spectra of ^{57}Fe in the case of correlated jump diffusion and electric field gradient rotation in an octahedral cage. (16 refs.)

72720 Mossbauer spectroscopy of laser annealed tellurium implanted silicon. I. ^{119}Sn and ^{125}Te. G.J.Kemerink, H.de Waard, L.Niesen, D.O.Boerma (Lab. voor Algemene Natuurkunde, Rijksuniv., Groningen, Netherlands).
Hyperfine Interactions (Netherlands), vol.14, no.1, p.37-51 (April 1983).
Laser annealed Te-implanted silicon has been investigated using ^{119}Sn and ^{125}Te Mossbauer spectroscopy. The ^{119}Sn Mossbauer spectra consist of a single lorentzian, known to be due to substitutional Sn atoms in Si, independent of the type of doping of the silicon. The results on ^{125}Te reveal at least two different components. In heavily doped n-type Si a single line component is observed with an isomer shift of 0.15(5) mm/s with respect to SnTe and an effective Debye temperature of 207(3)K. Heavy p-doping leads to another single line component with an isomer shift of $-0.13(5)$ mm/s and an effective Debye temperature of 232(3)K. These components are ascribed to the neutral and doubly positive charge state of substitutional Te atoms, respectively. (50 refs.)

72721 Mossbauer spectroscopy of laser annealed tellurium implanted silicon. II. ^{129}I. G.J.Kemerink, H.de Waard, L.Niesen, D.O.Boerma (Lab. voor Algemene Natuurkunde, Rijksuniv., Groningen, Netherlandsl).
Hyperfine Interactions (Netherlands), vol.14, no.1, p.53-88 (April 1983).
For pt.I see ibid., vol.14, p.37 (1983). Laser annealed ^{129m}Te-implanted silicon has been investigated using ^{129}I Mossbauer spectroscopy. At least three dope-dependent charge states of substantial iodine are found. For heavily doped p-type Si a single line component S_1, with isomer shift $S = 0.96(4)$ mm/s w.r.t. $Cu^{129}I$ and an effective Debye temperature $\theta' = 196(3)$K is observed. This component is attributed to I^{++}. For compensated Si a single line component, S_2, assigned to I^+, with $S = 2.39(4)$ mm/s and $\theta' = 170(3)$K is found. For n-type Si, a component S_3, characterized at 4.2K by $S = 2.15(4)$ mm/s and a quadrupole splitting $eQV_{zz}/h = 452(8)$ MHz $(\eta \simeq 0)$ is observed. At higher temperatures S_3 shows quadrupole relaxation and its recoilless fraction becomes strongly anisotropic. This behaviour is explained on the basis of a transition from a static to a dynamic Jahn-Teller distortion. Component S_3 has been attributed to I^0. In the spectra of compensated and n-type Si a less well-defined component Q, with parameters resembling those of S_3 but showing no quadrupole relaxation, is observed. This component has tentatively also been assigned to I^0. The results can be understood qualitatively on the basis of a simple MO-model. (30 refs.)

72722 On the Mossbauer isomer-shift studies of the electronic structure of semiconductors. E.Antoncik, Bing-lin Gu (Inst. of Phys., Univ. of Aarhus, Aarhus, Denmark).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.69-71 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The Mossbauer isomer shift provides a unique technique for studying the electronic structure of solids on the atomic scale and in many cases makes it possible to check the accuracy of the wave functions resulting from either the band-structure calculations or the solution of the impurity problem. Using a Green-function procedure based on a modified tight-binding method, the electronic configuration and the relevant isomer-shift values have been evaluated for several physically interesting cases. In particular, ^{119}Sn, ^{121}Sb, and ^{125}Te, representing either one of the components or an impurity in various A^NB^{8-N} semiconducting materials, are considered, and their local structure is discussed in detail. (9 refs.)

72723 Certain potentialities of double γ-nuclear magnetic resonance. T.Sh.Abesadze, A.Ya.Dzyublik.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.563-7 (April 1983). In Russian.
A theory is developed for the Mossbauer γ-quanta absorption and scattering by polarized ^{57}Fe nuclei in a crystal when the NMR transitions between sublevels of the ground nuclear state are induced. It is shown that this double γ-nuclear magnetic resonance can give information on the spin-spin interactions of the nuclei. (14 refs.)

76.90 OTHER TOPICS IN MAGNETIC RESONANCES AND RELAXATION

(inc. muon probe studies)

72724 Muon spin rotation in antiferromagnetic oxides. C.Boekema (Los Alamos Nat. Lab., Los Alamos, NM, USA), A.B.Denison, K.J.Ruegg.
J. Magn. & Magn. Mater. (Netherlands), vol.36, no.1-2, p.111-14 (April 1983).
Muon spin rotation results for antiferromagntic oxides with the corundum structure are discussed. An attempt to determine the muon stop sites and their chemical environment in these oxides is presented. In addition to the magnetic dipole contribution, a covalent contribution to the effective magnetic field at the muon site is considered. An interpretation of the muon hyperfine interactions in these oxides in terms of muon bond formation, analogous to the hydrogen-oxygen bonding, is given. (15 refs.)

Structure of muons trapped in aluminium .... See Entry 72344

77.00 DIELECTRIC PROPERTIES AND MATERIALS

(for conductivity phenomena, see 72.20 and 72.80)

77.20 PERMITTIVITY

72725 Contribution to the study of mixtures susceptible to microemulsion formation on account of their compositions by the definition of their dielectric permittivity at 9.455 GHz. J.M.Moreau, G.Delbos, A.M.Botteau (Lab. de Spectronomie Temporelle et Frequentielle, Univ. de Bordeaux I, Talence, France).
J. Mol. Liq. (Netherlands), vol.25, no.2, p.91-101 (April 1983). In French.
Dielectric studies of four component mixtures are rarely made on a great number of concentrations. The authors propose a dielectric behavior study of mixtures made with toluene-water-butanol-SDS, from specific mappings of permittivities which are plotted on pseudo ternary diagrams at 9.455 GHz. They draw different conclusions as to how at 9.455 GHz the variations of real and imaginary parts of permittivity involve the concentration of each component and the structure of the mixture. (49 refs.)

72726 Glass formation and properties of chalcogenide systems. XXVI. Permittivity and the structure of glasses As_xSe_{1-x} and Ge_xSe_{1-x}. A.Feltz, H.Aust, A.Blayer (Dept. of Chem., Friedrich Schiller Univ., Jena, Germany).
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.179-90 (May 1983).
Correlation between the real part of the dielectric constant and the structure of glasses in the systems As_xSe_{1-x} and Ge_xSe_{1-x} is reported. The mole polarization is calculated using the Sellmeyer approximation neglecting the Lorentz field. The vibrationally caused part of the permittivity which is obtained by subtraction of the mole refraction reflects ordered states in the investigated series. Besides the known crystalline compounds As_2Se_3 and As_4Se_4 the formation of the vitreous $AsSe_3$ and As_3Se_2 from the liquid state has to be supposed. In the system Ge_xSe_{1-x} the formation of the compounds $GeSe_2$ and Ge_2Se_3 is completed by $GeSe_4$ which as Ge_2Se_3 obviously only exists in the non-crystalline state. $GeTe_4$ has been reported as a metastable crystalline phase. The temperature dependence of ε_r of vitreous As_2Se_3 is tentatively interpreted in terms of the dipole orientation caused by conversion of the charge in valence alternation pairs. (51 refs.)

72727 On the dielectric Curie-Weiss law and diffuse phase transition in ferroelectrics. G.H.Jonker (Dept. of Electrical Engng., Twente Univ. of Technol., Enschede, Netherlands).
Mater. Res. Bull. (USA), vol.18, no.3, p.301-8 (March 1983).
A simple derivation of parabolic $1/\epsilon_r$-T curves is obtained by reconsidering the origin of the dielectric Curie-Weiss law. The only assumption needed is the introduction of a non-linear temperature dependence of the macroscopic dielectric polarization in the macroscopic Clausius-Mossotti equation. (12 refs.)

72728 The influence of microstructure on the dielectric spectra of ferrites. G.P.Kramar, Ya.I.Panova, V.V.Passynkov (V.I. Ulyanov (Lenin), Leningrad.Electrical Engng. Inst.,USSR).
Phys. Status Solidi a (Germany), vol.76, no.1, p.95-100 (16 March 1983).
Ceramic specimens of Mn-Zn ferrites of different compositions and microstructures are investigated in the frequency range from 100 Hz to 20 MHz and at temperatures from 20 to 130°C. Mathematical expressions (taking into account the actual distribution of grain sizes in the specimen) are proposed to describe the frequency dependence of the complex permittivity components. It is shown that the dielectric spectrum of polycrystalline ferrites reveals two relaxation processes. The process of grain surface state recharge gives the main contribution to the static permittivity and its parameters essentially depend on the firing temperature. The parameters of the high-frequency relaxation process due to the existence of low-conductivity layers of grain surfaces correlate with the parameters of the microstructure. (5 refs.)

77.30 POLARIZATION AND DEPOLARIZATION EFFECTS

72729 Phenomenological theory of shock-induced polarization. I. M.de Icaza-Herrera (Inst. de Fisica, Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).
J. Appl. Phys. (USA), vol.54, no.5, p.2352-9 (May 1983).
After reviewing the actual state of knowledge of Shock-Induced Polarization, the authors discuss the validity of Allison's theory, specially concerning the physical meaning of his three parameters P_s^0, K', and τ. They then propose another approach, splitting the electric field in the dielectric into two components: the electric field (uniform) produced by the charges in the plates, and the electric field (nonuniform) produced by the polarization charges. This enables one to relate the line integral of polarization across the dielectric with an easily measurable potential difference $F(t)$. Its time derivative $F(t)$ is then found to be related with the polarization discontinuity across the shock front, without making any assumptions on the space or time dependence of polarization. Later, the authors introduce the dielectric properties in a Lagrangian frame, which are finally inserted, in Eulerian form, in $F(t)$. Four equations for $F(t)$ are obtained, depending on the relaxing properties of the nonshocked medium and on the mechanism producing the polarization: the dipolar orientation or the bond scission model. The authors also present the $F(t)$ equation when there is no reflected shock at the second electrode, the entire dielectric being shocked. (26 refs.)

77.40 DIELECTRIC LOSS AND RELAXATION

72730 An equation to calculate the equilibrium constant of 1:1 complexes from dielectric relaxation measurements. A.Singh, M.C.Saxena (Phys. Dept., Lucknow Univ., Lucknow, India).
J. Mol. Liq. (Netherlands), vol.25, no.2, p.81-90 (April 1983).
The dielectric measurements of 1:1 mixture of acetates, namely ethyl acetate, butyl acetate and benzyl acetate and phenol and n-butyl alcohol in carbon tetrachloride at 9.8 GHz microwave frequency were carried out. A method has been proposed to calculate the equilibrium constant of 1:1 hydrogen bonded complexes. These values are in close agreement to the values obtained using the Few and Smith method (1949). (18 refs.)

72731 Intramolecular relaxation processes of some aromatic esters. M.A.Kashem, H.A.Khwaja, S.Walker (Lakehead Univ., Thunder Bay, Ontario, Canada).
J. Mol. Liq. (Netherlands), vol.25, no.2, p.129-37 (April 1983).
Dielectric absorption measurements have been made in the frequency range 10^2-10^5 Hz over a variety of temperatures on dimethyl terephthalate, dimethyl 2,6-naphthalene dicarboxylate, methyl and ethyl benzoates, ethyl-p-chlorobenzoate, methyl and ethyl cinnamates, and methyl salicylate. The solutes have been dispersed in a polystyrene matrix and in four cases also in a polyphenyl ether medium. One compound, methyl salicylate, was also examined as a pure compressed solid. The Eyring parameters have been determined and employed to characterize the relaxation processes. The results are discussed in terms of molecular and intramolecular processes involving the whole ester grouping or the methoxy group or an overlap of both processes. In the case of methyl salicylate the barrier for the methoxy group relaxation has been determined in the compressed solid state. (28 refs.)

72732 On the dielectric properties of semiconducting materials as obtained from impedance measurements on Schottky barriers. F.Fransen (Rijksuniv. Gent, Gent, Belgium), M.J.Madou, W.H.Laflere, F.Cardon, W.P.Gomes.
J. Phys. D (GB), vol.16, no.5, p.879-88 (14 May 1983).
Dielectric properties of several semiconducting materials were studied by impedance measurements of metal/semiconductor and electrolyte/semiconductor Schottky barriers. Power laws of the frequency were observed analogous to those reported for insulating materials. Also the relationship between the tangent of the loss angle and the bandgap of the semiconductor appeared to be similar to that observed on insulators. The results indicate that the residual frequency dispersion of the Schottky-barrier capacitance, persisting after careful pretreatment of the semiconductor surface, can be ascribed to the dielectric properties of the space-charge layer. (16 refs.)

72733 Dielectric relaxation of adsorbed water in microcrystalline cellulose. M.Kent, W.Meyer (Ministry of Agriculture, Fisheries & Food, Torry Res. Station, Aberdeen, Scotland).
J. Phys. D (GB), vol.16, no.5, p.915-25 (14 May 1983).
Measurements have been made to determine the dielectric properties of hydrated microcrystalline cellulose (MCC) in a frequency range from 200 MHz to 18 GHz. A broad dispersion region has been observed, characterised by a Cole-Davidson relaxation. The activation enthalpy of the charateristic relaxation time has been determined from the temperature dependence of the dispersion and corresponds roughly to two hydrogen bonds. The dispersion is identified as being due to the absorbed water and is shown to be moisture content dependent. (15 refs.)

72734 Intramolecular relaxation processes of benzophenone and related molecules in glassy media. M.A.Desando, D.L.Gourlay, S.Walker (Dept. of Chem., Lakehead Univ., Thunder Bay, Ontario, Canada).
J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.4, p.559-70 (April 1983).
Radiofrequency (10^2-10^5 Hz), variable temperature (77-333K) dielectric loss measurements were performed for a series of diaryl ketones and pyridyl ethylenes in polystyrene, and in the case of benzophenone and 2,3,4,5,6-pentadeuterobenzophenone also in *o*-terphenyl and in Santovac {bis[*m*(*m*-phenoxy phenoxy)phenyl]ether}. An intramolecular process with a low enthalpy of activation ($\Delta H_E \approx 20$ kJ mol^{-1}) was observed in the benzophenones and $\Delta H_E \approx 30$ kJ mol^{-1} for bis(2-pyridyl) ketone and 1,2-bis(2- and 4-pyridyl) ethylene. A mesomeric process would seem to be the most probable intramolecular mechanism through which these symmetrically substituted ketone and ethylene derivatives relax. The observed relaxation processes seem to be unaffected by varying the medium. (31 refs.)

77.50 DIELECTRIC BREAKDOWN AND SPACE-CHARGE EFFECTS

72735 Electrical properties of post-annealed thin SiO_2 films. S.S.Cohen (Corporate Res. & Dev., General Electric Co., Schenectady, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.929-32 (April 1983).
Very thin films of silicon dioxide grown in a conventional dry oxidation process often suffer from poor electrical quality due to the presence of various defects. A low dielectric breakdown is, in particular, detrimental to the operation of many electronic devices. The author has attempted to improve this situation by modifying the dry oxidation process. He shows that oxides grown in oxygen ambient and under atmospheric pressure, which are postannealed for a long period of time in an inert atmosphere and then reoxidized for a short time, have considerably improved values of both the magnitude and distribution of the electric field at the dielectric breakdown. Very few low-field dielectric breakdown events are encountered and the breakdown field histogram assumes a very narrow shape. (18 refs.)

72736 The role of electrostatic and hydrodynamic forces in the electrical breakdown of liquid dielectrics. P.K.Watson (Xerox Corp., Rochester, NY, USA).
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.65-70
Optical studies of pre-breakdown events in point-plane gaps in insulating liquids enable one to distinguish at least three stages in the breakdown process: (i) The creation of a low density region adjacent to the point electrode. (ii) The growth of a wave-like disturbance in the surface of the low density region, which is interpreted as an electrohydrodynamic instability. (iii) The runaway growth of the instability leading to streamers which bridge the gap and cause the actual breakdown. This analysis is mainly concerned with the electrostatic aspects of these three stages in the breakdown process. (16 refs.)

77.70 PYROELECTRIC AND ELECTROCALORIC EFFECTS

72738 Temperature changes of the primary and secondary pyroelectric effect in $LiKSO_4$ crystal (100-300K). B.Mroz, T.Krajewski, T.Breczewski (Inst. of Phys., A. Mickiewicz Univ., Poznan, Poland).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.445-8 (April 1983).
Anomalous changes of pyroelectric effect in $LiKSO_4$ crystals in the temperature region between 100 and 300K were analysed in detail. It was found that the change in sign of the total pyroelectric effect coefficient p_3^{σ} of $LiKSO_4$ crystals at about 190K is mainly caused by the change in sign of p_3^{π} coefficient, which defines the magnitude of the primary pyroelectric effect in this crystal. The temperature changes of p_3^{s} coefficient, defining the magnitude of the secondary pyroelectric effect in $LiKSO_4$ crystals, were found to be inessential in the phenomenon analysed. (12 refs.)

Dielectric and pyroelectric properties of doped triglycine sulphate crystals [for infrared detectors] .... See Entry 72742

77.80 FERROELECTRICITY AND ANTIFERROELECTRICITY

72739 SbSI and other ferroelectric $A^VB^{VI}C^{VII}$ materials. E.I.Gerzanich (Uzhgorod State Univ., Uzhgorod, USSR), V.A.Lyakhovitskaya, V.M.Fridkin, B.A.Popovkin.
In book: *Current topics in materials science. Vol.10*, E.Kaldis [Ed.], p.55-190. Amsterdam, Netherlands: North-Holland (1982), vi+515 pp. [0 444 86321 4]
The authors' survey indicates that by now the investigation of ferroelectric of $A^VB^{VI}C^{VII}$ type is of considerable fundamental and applied interest. The combination of ferroelectric, semiconducting and photoconducting properties of SbSI and related compounds allowed the first discovery of photoferroelectric phenomena. One of these phenomena is the effect of photoactive illumination and the corresponding creation of non-equilibrium carriers on the Curie temperature, spontaneous polarization and other macroscopic properties of ferroelectrics (photodomain effect, photoswitching etc.). (324 refs.)

77.80B Transitions and Curie point

72740 Detection of the incommensurate modulation of the hydrogen-bond double-minimum potential in the antiferroelectric phase of NH_4HSeO_4. I.P.Aleksandrova, O.V.Rosanov, A.A.Sukhovsky, Yu.N.Moskvich (L.V. Kirensky Inst. of Phys., Krasnoyarsk, USSR).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.339-42 (9 May 1983).
An incommensurate antiferroelectric phase in the NH_4HSeO_4 crystal was found by ^{77}Se high-resolution NMR in the temperature range 250-262K. An anomalous line-shape continuum limited by two-edge singularities is observed in this region and described by plane-wave modulation. A model where the asymmetry of proton occupation in the H-bond system is modulated along a certain direction is discussed. The incommensurate structure is metastable. (15 refs.)

72741 Dynamic critical behavior of ferroelectric triglycine sulfate from dielectric loss measurements. R.Garcia, J.A.Gonzalo (Dept. de Optica y Estructura de la Materia, Univ. Autonoma de Madrid, Madrid, Spain).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1501-4 (9 May 1983).
Measurements of the dielectric loss in triglycine sulfate are shown to yield information on the critical temperature dependence of the relaxation time, $\tau(t)$, where $t \equiv (T-T_c)/T_c$. The data indicate a power law $\tau^{-1}(t) \sim t^x$, where $x = 0.656 \pm 0.025 \simeq {}^2/_3$ for $7 \times 10^{-2} < \Delta T < 1.5°C$ at $T > T_c$. $\tau(t)$ does not diverge at T_c, in accordance with theoretical considerations. For $T < T_c$ the data suggest a similar behavior. The role of logarithmic corrections is analyzed, and estimates of the correlation length amplitude $\xi_0 \simeq 7.86$ Å and the dipole-dipole constant $g \simeq 3.44 \times 10^{-7}$ Å^{-2} are obtained. 72743 Multiphoton processes in light absorption by homopolar crystals. Self-trapping and classical solutions [for multiphoton read multiphonon]. A.S.Ioselevich (L.D. Landau Inst. of Theoretical Phys., Acad. of Sci., USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.415-21 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.743-55 (Aug. 1982). [received: May 1983]
The absorption of light with a photon energy deficit $\Delta = E_g \rightarrow \hbar\Omega \gg \hbar\omega_{,0}$, with participation of a large number of optical strain phonons at frequency ω_0, is considered. It is shown that at low temperatures $T < \hbar\omega_0$ two alternate mechanisms exist. The first is connected with absorption of the required number of phonons from the thermostat, and the second with tunnel self-trapping. The Δ-dependent temperature limit $T^* < \hbar\omega_0$ above and below which the first and second process dominate, respectively, is found. The existence of several absorption mechanisms manifests itself in the fact that the classical solution that describes a multiphonon transition of an electron-phonon systems is not unique. The absorption coefficient agrees well with the Urbach rule at $T^* < T < \hbar\omega_0$ and becomes practically independent of temperature at $T < T^*$. At $T > \hbar\omega_0$ the absorption is accompanied by formation of an optical classical fluctuation that has a level of energy $-\Delta$. (12 refs.)

78.20D Optical constants and parameters

72744 Optical constants of fused silica and sapphire from 0.3 to 25 µm. M.L.Lang, W.L.Wolfe (Ball Brothers, Boulder, CO, USA).
Appl. Opt. (USA), vol.22, no.9, p.1267-8 (1 May 1983).
The optical constants of fused silica and sapphire have been measured in regions where they are transparent and where they are opaque—from 0.3 to 50 µm. The technique used was the Kramers-Kronig method whereby the complex reflectivity (reflectance) was measured at normal incidence over the entire spectrum. A study of the data for the optical constants n and k of fused silica shows a strong absorption band centered at ~9 µm and a strong refractive-index peak just short of 10 µm. This is consistent with the well-known reststrahlen peak of quartz. A second strong and broader peak occurs at 22 µm, and the corresponding refractive-index peak is at ~24 µm. The corresponding two curves for sapphire show that absorption occurs in two strong lines at ~18 and ~24 µm with subsidiary peaks at ~16 and ~19 µm. There are corresponding strong index peaks. The measurements seem to be of satisfactory accuracy. (10 refs.)

72745 Photo-induced changes of optical properties in noncrystalline As-S system films. Sheng Lian-gen, Chen Xue-xian, Xiao Jia-ning, Chen Ju-fang (Shanghai Inst. of Ceramics, Acad. Sinica, Shanghai, China).
Chin. Phys. (USA), vol.3, no.1, p.149-54 (Jan.-March 1983). [received: May 1983]
The changes in optical properties of As-S films with different compositions during exposure to Ar^+ laser light have been studied. The experimental results show that the photo-induced change of the optical properties is a volume effect and is the largest for As_2S_3 film (among various As/S ratios). The kinetics of the structural change is discussed. The refractive index variations in an as-deposited As_2S_3 film at annealing-exposure cycles have been studied. The reversible part of the variation is determined to be about 0.03, and the irreversible about 0.1. (20 refs.)

72746 Optical and other physical properties of fluorophosphate glass containing $Al(PO_3)_3$. Jiang Yasi, Jiang Fusong, Gan Fuxi (Shanghai Inst. of Optics & Fine Mech., Acad. Sinica, Shanghai, China).
Chin. Phys. (USA), vol.3, no.1, p.162-8 (Jan.-March 1983). [received: May 1983]
Fluorophosphate glass has found applications as optical glass and laser material. In the present work, the optical and other physical properties of the fluorophosphate glass containing $Al(PO_3)_3$ have been investigated and the results are then correlated with the glass structure. The low $Al(PO_3)_3$ content fluorophosphate glass, in which the network structure has been heavily destroyed (the destroyed region), the variation of the glass properties, and the effect of various fluorides on the properties are similar to those of the oxide glass in destroyed region. The special role of LiF, MgF_2, AlF_3 is also reflected on the variation of the physical properties. Comparisons with silicate and borate glasses with high contents of glass formers have indicated that the electrostatic attraction between cations and anions plays more important role in the variation of the properties of the fluorophosphate glass with low $Al(PO_3)_3$ content. The position of the studied glass in the n_d vs. ν diagram is plotted, the partial properties of the studied glass are given and compared with some literature data, and the variation of the partial properties has been related to the $Al(PO_3)_3$ content. (12 refs.)

72747 Refractive index increment of polymers in ternary systems with special reference to diffusion measurements. R.Rymden, J.Carlfors (Inst. of Phys. Chem., Univ. of Uppsala, Uppsala, Sweden).
Polym. Commun. (GB), vol.24, no.4, p.114-17 (April 1983).
A study was made of how the refractive index increment dn/dc, of hydroxypropyl cellulose (HPC) and sodium carboxymethyl cellulose (NaCMC) in aqueous solution is affected by the addition of various glucose derivatives. It was found that dn/dc of HPC decreased with addition of a third component while dn/dc of NaCMC was unaffected. These findings are relevant in connection with diffusion of probe molecules in polymer solutions when using optical methods to monitor the relaxation of the initial concentration gradient. (11 refs.)

72748 Non-linear refraction in magnetised III-V semiconductors. P.K.Sen (Dept. of Phys., Heriot-Watt Univ., Edinburgh, Scotland).
J. Phys. C (GB), vol.16, no.13, p.2603-10 (10 May 1983).
Using the coherent radiation-exciton interaction model, the phenomenon of non-linear refraction has been investigated analytically in the important III-V semiconductors duly irradiated by laser beams with photon energies in the vicinity of the crystal band edges in the presence of a large steady magnetic field. Phenomenological introduction of a damping constant is shown to explain the saturation mechanism. The results can be compared with those obtainable from the direct saturation model. (20 refs.)

72749 The temperature dependence of the refractive indices of fused silica and crystal quartz. T.Toyoda, M.Yabe (Fuji Electric Corporate Res. & Dev. Ltd., Nagasaka, Yokosuka City, Japan).
J. Phys. D (GB), vol.16, no.5, p.L97-100 (14 May 1983).
The temperature dependence of the refractive indices of high-purity fused silica and crystal quartz was measured in the 450-1600 nm wavelength range and at temperatures from room temperature to 400°C. The average thermal coefficients of the refractive indices of those materials show opposite sign. The wavelength dependence of the coefficient in fused silica is smaller than that in crystal quartz. (4 refs.)

72750 Optical properties of GaAs, GaP, InP, and Si in the 300-1000K temperature range. D.I.Bilenko, O.Ya.Belobrovaya, B.A.Dvorkin, V.D.Tsiporukha.
Opt. & Spectrosc. (USA), vol.53, no.3, p.276-80 (Sept. 1982). Translation of: *Opt. & Spektrosk. (USSR)*, vol.53, no.3, p.497-75 (Sept. 1982). [received: May 1983]
The temperature dependence of the refractive index n and absorption coefficient α of common semiconducting materials (GaAs, GaP, InP, and Si) were studied. The experimental results were obtained at wavelengths of 0.6328, 1.15, and 3.39 µ in the 300-1000K temperature range. The essential depen-

dence of the temperature behavior of n and α on the width of the energy gap between Γ and X valleys, on the temperature changes of the electronic spectrum, on alloying, and on the mechanism of carrier scattering are established experimentally and explained. (20 refs.)

72751 Dispersion of the indices of refraction and birefringence of cadmium thiogallate. L.M.Suslikov, Z.P.Gadmashi, D.Sh.Kovach, V.Yu.Slivka.
Opt. & Spectrosc. (USA), vol.53, no.3, p.283-7 (Sept. 1982). Translation of: *Opt. & Spektrosk. (USSR)*, vol.53, no.3, p.480-8 (Sept. 1982). [received: May 1983]
Experimental data are presented on the dispersion of the ordinary n_o and extraordinary n_e indices of refraction of cadmium thiogallate obtained by the prism and interference methods in the region of transparency of the compound. The spectral dependence of the birefringence of $CdGa_2S_4$ in the same region of the spectrum is also studied. Intersection of the dispersion curves of n_o and n_e at $\lambda=4882$ Å is a typical feature of the data obtained. Analysis is made on the data using the generalized Wemple-DiDomeniko single-oscillator model. The magnitude and sign of the birefringence of $CdGa_2S_4$ and the potential application of this crystal in nonlinear optics are discussed. (34 refs.)

72752 Optical absorption in single-crystal metastable $(GaAs)_{1-x}(Ge_2)_x$ alloys; evidence for a zinc-blende-diamond order-disorder transition. K.E.Newman, A.Lastras-Martinez, B.Kramer, S.A.Barnett, M.A.Ray, J.D.Dow, J.E.Greene (Univ. of Illinois, Urbana, IL, USA), P.M.Raccah.
Phys. Rev. Lett. (USA), vol.50, no.19, p.1466-9 (9 May 1983).
Single-crystal metastable $(GaAs)_{1-x}(Ge_2)_x$ alloys with $0<x<1$ have been grown on (100) GaAs substrates by use of ultrahigh-vacuum ion-beam sputter deposition. Optical-absorption measurements showed that the direct gap E_0 exhibited a large negative V-shaped bowing as a function of x with a minimum $E_0 \simeq 0.5$ eV near $x=0.3$. A zinc-blende to diamond-lattice order-disorder transition model is proposed as a possible explanation for these results. (15 refs.)

72753 Optical properties of K_2SeO_4 in the vicinity of phase transitions. S.Pacesova, B.Brezina, L.Jastrabik (Inst. of Phys., Czechoslovak Acad. of Sci., Prague, Czechoslovakia).
Phys. Status Solidi b (Germany), vol.116, no.2, p.645-52 (1 April 1983).
The temperature dependence of the absorption edge of K_2SeO_4 is measured in the range 300 to 4.2K. In this temperature range the dependence of the absorption coefficient on the energy of photons and temperature is described by Urbach's rule. The magnitudes of the band gap obtained are $E^{\parallel}+6.06$ and $E^{\perp}=6.14$ eV for light polarized parallel and perpendicular to the a-axis. The temperature gradient of the band gap $(\partial E/\partial T)^{\parallel,\perp}$ reveals a jump at the paraelectric-incommensurate phase transition $T_2=129.5$K for both polarizations of incident light in agreement with the second-order nature of the phase transition. In the paraelectric phase, phonons with eigenfrequencies $\omega^{\parallel}=218$ cm^{-1} and $\omega^{\perp}=181$ cm^{-1} are interacting with the optical transitions. A switch-over to the optical phonon of frequency $\omega^{\parallel,\perp}=92$ cm^{-1} is observed at T_2 together with the change of the electron-optical-phonon coupling constants indicating the increase of the ionic character of the bonds in the incommensurate phase between the K^+ ions and the $(SeO_4)^{2-}$ tetrahedral groups. (9 refs.)

72754 Optical constants of pure and heavily doped silicon and germanium: electronic interband transitions. L.Vina, M.Cardona (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.356-8 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The technique of Fourier analysis ellipsometry has been applied to pure and heavily doped n- and p-type Ge and Si (doping up to $\approx 10^{20}$ cm^{-3}) to obtain accurate spectra of ϵ_1 and ϵ_2. The authors have studied the shift and broadening of the E_1 (3.4 eV in Si, 2.1-2.3 eV in Ge) and E_2 ($\sim$4.3 eV in both) with doping. All these peaks shift to lower photon energies and broaden with doping. These shifts amount to $\sim$0.05 eV for dopings of 10^{20} cm^{-3}. The results are discussed in terms of the perturbation produced by the ionized impurities. (11 refs.)

72755 Surface transition regions and visible-near UV optical properties of some semiconductors. D.E.Aspnes (Bell Labs., Murray Hill, NJ, USA).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.359-61 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Spectroscopic ellipsometry is used to investigate transition regions at semiconductor surfaces where the dielectric response is changing from bulk to ambient values. Microscopically rough but atomically clean transition regions are shown to be described by effective medium theory. A comparison for ⟨100⟩, ⟨110⟩, and ⟨111⟩ Si surfaces shows that chemical processing yields lower effective transition region widths than processing in ultrahigh vacuum. Plasma sum rules evaluated from more accurate ϵ data obtained here are compared to earlier calculations in the literature. (8 refs.)

72756 The 'missing' electromagnetic wave and the additional boundary conditions for light in a crystal. S.I.Pekar, V.J.Pipa (Inst. of Semiconductors, Acad. of Sci., Kiev, Ukrainian SSR).
Solid State Commun. (USA), vol.46, no.4, p.363-5 (April 1983).
Light penetrating from vacuum into a crystal gives rise to a non-uniform wave in both media that has not been taken into account up to now. Its wavevector $\mathbf{k}$ normal projection is imaginary and $\mathbf{k}^2=0$. The allowance for this wave makes it for the first time possible in the general case to satisfy all the additional boundary conditions of the additional light wave theory. (4 refs.)

72757 Study of the extinction and scattering of light near the critical point. L.V.Adzhemyan, L.Ts.Adzhemyan, L.Z.Zubkov, V.P.Romanov (Leningrad State Univ., Leningrad, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.295-8 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.539-44 (Aug. 1982). [received: May 1983]
The extinction and scattering of light in the vicinity of the critical stratification point are studied in the strongly opalescing BMOAB-isooctane mixture. Owing to the large scattering coefficient, multiple scattering of light plays a major role practically throughout the whole temperature range studied. An iteration procedure is proposed and used for a combined reduction of the experimental data on the basis of the temperature dependence of the transmitted-light intensity and the light-scattering indicatrix. This reduction permits the critical parameters to be determined with good accuracy and diminishes their variance by several times compared to that attained when the results of each of the experiments are analyzed separately. (5 refs.)

72758 Optics of the blue phase of cholesteric liquid crystals. V.A.Belyakov, V.E.Dmitrenko, S.M.Osadchii (All-Union Res. Inst. for Physicotech. & Radiotech. Measurements, USSR).
Sov. Phys.-JETP (USA), vol.56, no.2, p.322-30 (Aug. 1982). Translation of: *Zh. Eksp. & Teor. Fiz. (USSR)*, vol.83, no.2, p.585-600 (Aug. 1982). [received: May 1983]
A theory is developed for the optical properties of the blue phases of cholesteric liquid crystals, with account taken of the symmetry restrictions on their experimentally determined structures. The diffraction features of the optics of blue phases (possible reflections and their polarization properties) are found for all the admissible structures, and their optical properties are analytically described within the framework of the dynamic theory. The experimental data are analyzed. The limitations on the blue phase and on the details of these structures, which follow from the experimental data, are indicated. The importance of optical and particularly polarization measurements for the unambiguous determination of the blue-phase structures are noted, as are the possibilities of using the effects of multiple scattering to extract quantitatively more exact structural information.

72759 Optical properties of KDP and DKDP crystals grown at high rates. V.I.Bespalov, V.I.Bredikhin, V.P.Ershov, V.I.Katsman, N.V.Kiseleva, S.P.Kuznetsov (Inst. of Appl. Phys., Acad. of Sci., Gorki, USSR).
Sov. J. Quantum Electron. (USA), vol.12, no.11, p.1527-8 (Nov. 1982). Translation of: *Kvantovaya Elektron., Moskva (USSR)*, vol.9, no.11, p.2343-5 (Nov. 1982). [received: May 1983]
An investigation was made of the transparency, homogeneity, and optical strength of KDP and DKDP crystals grown at rates much higher (by a factor of 25-30) than usual. A comparison was made with the properties of crystals grown at conventional rates. The results indicated that, in principle, it should be possible to grow in this way crystals suitable for use in quantum electronics. (6 refs.)

72760 Some optical characteristics of powdered tellurites of rare-earth elements. A.L.Voloshina, L.A.Ivanchenko, V.A.Obolonchik, E.S.Lugovskaya (Inst. of Materials Sci., Acad. of Sci., Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.728-31 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.53-7 (Sept. 1982). [received: March 1983]
As a result of the crystallization of La tellurite specimens accompanying the raising of heat treatment temperature, the refractive index of the compound increased, isotropic particles with cubic structure symmetry became replaced by grains of long prismatic shape, birefringence appeared, and the refractive index became dependent on orientation. Judged by the character of their reaction with light, compounds of the $Ln_2Te_3O_9$ type may be classed as semiconductors with forbidden zones of widths $h\nu_0 \geq 3.8$ eV. It is shown, taking $La_2Te_3O_9$ as an example, that the heat treatment of air-dry specimens at temperatures above 400°C reduces the width of the forbidden zones of the compounds investigated and increases their light absorption coefficients at photon ernergies $h\nu>4$ eV. (8 refs.)

72761 Electron microscopic and ellipsometric studies on oxidized aluminium layers. P.B.Barna, Z.Bodo, G.Gergely, D.Szigethy (Res. Inst. for Tech. Phys., Hungarian Acad. of Sci., Budapest, Hungary), J.Adam, P.Jakab.
Vacuum (GB), vol.33, no.1-2, p.93-7 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Epitaxial and polycrystalline Al thin films were deposited in HV on cleaved mica and glass substrates. The Al films were oxidized by thermal and electrolytic processes. The optical constants n and k of virgin and oxidized Al films have been determined by ellipsometry in the 365-579 nm wave length range at the four intensive Hg lines. The apparent values of n and k of the Al films exhibited some correlations with their microstructure revealed by electron microscopy explaining discrepancies in contradictory literature data. Using the same optical constants for the Al substrate after oxidation, a reasonable agreement of the oxide thickness was found at the four Hg lines, with the refractive index $n_{ox}=1.77$, evaluating the ellipsometric measurements. Ellipsometric studies were completed by reflectance measurements. (14 refs.)

78.20E Optical rotatory power

72762 Optical activity and circular dichroism spectra of pure and deuterated Rochelle salt crystals. M.Koralewski, M.Mroz (Inst. of Phys., A. Mickiewicz Univ., Poznan, Poland).
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.507-17 (April 1983).
Presents the UV absorption, optical rotatory dispersion (ORD) and circular dichroism (CD) spectra of pure and deuterated Rochelle salt single crystals and aqueous solutions within the UV and visible region. Similar results for tartaric acid crystals and its aqueous solution are included for comparison. The interpretation of the observed ORD and CD bands is given together with the origin of optical activity (OA) of the compounds under investigation.

Also, the relation between OA and spontaneous polarization, P_s is discussed. (28 refs.)

72763 Temperature studies of optical properties of cadmium diphosphide crystals. V.G.Fedotov, A.G.Bychkov, D.N.Karlikov, L.M.Gorynya, A.U.Sheleg, E.M.Smolyarenko, Z.K.Orlik (Inst. of Phys. of Solids & Semiconductors, Acad. of Sci., Minsk, Belorussian SSR).
Phys. Status Solidi a (Germany), vol.76, no.1, p.121-6 (16 March 1983).
The natural optical activity (NOA) and the refractive index are measured in the temperature intervals of 4.2 to 400K and of 293 to 400K, respectively. The dispersion of the NOA is best approximated by a single-term Drude formula. The parameters of dispersion formulas are given for various temperatures. A temperature dependence of NOA in CdP_2 is found. The temperature variation of the CdP_2 rotational ability is shown to be mainly due to the temperature shift of the corresponding optically active band at E=2.4 eV. In the 360 to 380K temperature range a break is observed in the temperature dependence of the specific rotation and the refrative index, while the temperature dependence of the gyration tensor component displays a characteristic feature with well defined maxima, which indicates the presence of a phase transition in CdP_2 crystals in this temperature range. 78.20F Birefringence

(inc. stress birefringence, flow birefringence, etc)

72764 Molecular quadrupole moment and effective-quadrupole-centre of fluorobenzene. G.R.Dennis, I.R.Gentle, G.L.D.Ritchie (School of Chem., Univ. of Sydney, Sydney, New South Wales, Australia).
J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.4, p.529-38 (April 1983).
Measurements of the infinite-dilution molar field-gradient birefringence constant, Kerr constant and Cotton-Mouton constant of fluorobenzene as a solute in carbon tetrachloride at 25°C and at two visible-spectrum wavelengths (441.6 and 632.8 nm) are reported. Analysis of the observations, in conjunction with other known electric and magnetic properties of fluorobenzene, yields the out-of-plane component of the molecular quadrupole moment relative to the effective-quadrupole-centre, establishes that at both wavelengths the effective-quadrupole-centre is close to the centre-of-ring, and permits the evaluation of a combination of elements of the dipole-quadrupole polarisability, **A**, and the optical-activity tensor, **G′**. A complete, though approximate, specification of the centre-of-mass quadrupole moment can be obtained by invoking reasoning due to Shoemaker and Flygare (1969); the result ($\Theta_{xx}/10^{-40}$ C m^2, $\Theta_{yy}/10^{-40}$ C m^2, $\Theta_{zz}/10^{-40}$ C m^2) now found (-1.5 ± 2.9, 22.5 ± 2.7, -21.0 ± 1.0) is at variance with that from the microwave Zeeman effect of this molecule (-6.3 ± 2.7, 17.0 ± 5.0, -10.7 ± 5.0). (33 refs.)

72765 Field-gradient-induced birefringence in dilute solutions of furan, thiophen and selenophen in cyclohexane. G.R.Dennis, I.R.Gentle, G.L.D.Ritchie (School of Chem., Univ. of Sydney, Sydney, New South Wales, Australia), C.G.Andrieu.
J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.4, p.539-45 (April 1983).
Measurements of the infinite-dilution molar field-gradient birefringence constants, Kerr constants and Cotton-Mouton constants of furan, thiophen and selenophen as solutes in cyclohexane at 298K and 632.8 nm are reported. Analysis of the observations, in conjunction with other known electric and magnetic properties of these molecules, yields for each the out-of-plane component of the quadrupole moment relative to the effective-quadrupole-centre. Combination of these results with centre-of-mass quadrupole moments from microwave Zeeman spectroscopic studies leads to low-precision estimates of the position of the effective-quadrupole-centre and of the relevant combination of elements of the **A** and **G′** tensors. (38 refs.)

72766 Birefringence and dichroism in Zn_3P_2. Z.Gumienny, M.Kiwus, J.Misiewicz (Inst. of Phys., Tech. Univ. of Wroclaw, Wroclaw, Poland).
Opt. Appl. (Poland), vol.12, no.3-4, p.419-26 (1982).
Birefringence and dichroism measurements in Zn_3P_2 at 10, 80 and 300K are described. A simple theoretical model is used to explain the results obtained. (8 refs.)

72767 Nonlinear photoelasticity of crystals in the exciton resonance region. R.A.Ayukhanov, Yu.V.Gulyaev, G.N.Shkerdin (Inst. of Radio Engng. & Electronics, Acad. of Sci., Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1402-3 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2174-6 (Dec. 1982). [received: May 1983]
When the frequency of light approaches the resonance absorption region of an insulator, the linear photoelasticity coefficients increase strongly and the effect is particularly important in the exciton absorption region. The authors study the nonlinear photoelasticity in the case of resonance involving exciton states. (8 refs.)

72768 On the nature of piezooptical coefficient temperature anomalies in triglycine sulphate group crystals. B.G.Mytsyk, N.A.Romanyuk.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.538-42 (April 1983). In Russian.
Temperature dependences of piezooptical coefficients have been determined for triglycine sulphate with an analysis of the estimated anomalies. The role of elasticity in the piezooptical experiment and the spectral dependence of the piezooptical constants are discussed. (10 refs.)

72769 Electroabsorption by Stark effect on room-temperature excitons in GaAs/GaAlAs multiple quantum well structures. D.S.Chemla, T.C.Damen, D.A.B.Miller (Bell Labs., Holmdel, NJ, USA), A.C.Gossard, W.Wiegmann.
Appl. Phys. Lett. (USA), vol.42, no.10, p.864-6 (15 May 1983).
The authors report the first observation of electroabsorption in GaAs/GaAsAs multiple quantum well structures. They have been able to induce Stark shifts for room-temperature excitation resonances of ~10 meV for applied field $\sim1.6\times10^4$ V/cm in a sample with 96-Å GaAs layers, giving large changes in optical absorption (e.g., a factor of 5 or $\sim4\times10^3$ cm^{-1} increase). This should permit optical modulators with micron path lengths and potentially very fast operation. (8 refs.)

72770 Electro-optic effects of (Pb, La)(Zr, Ti)O_3 thin films prepared by RF planar magnetron sputtering. H.Adachi, T.Kawaguchi, K.Setsune, K.Ohji, K.Wasa (Central Res. Labs., Matsushita Electric Industrial Co. Ltd., Osaka, Japan).
Appl. Phys. Lett. (USA), vol.42, no.10, p.867-8 (15 May 1983).
Epitaxial(Pb, La)(Zr, Ti)O_3 thin films were grown successfully on (0001) sapphire substrates at below 600°C. High quadratic electro-optic coefficient of 0.8×10^{-16} (m/V)^2 was also obtained at 6328 Å. The RF planar magnetron sputtering progress improved the quality of the film, which will be suitable for thin-film integrated optic devices. (8 refs.)

72771 Electroabsorption in chromium-doped *p*-type GaAs. V.A.Morozova, V.V.Ostroborodova, V.N.Sheremet'ev (M.V. Lomonosov State Univ., Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1394-5 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2162-4 (Dec. 1982). [received: May 1983]
The published information on the energy position of the first acceptor (1A) level of Cr in GaAs is extensive but contradictory: $\epsilon_{1Ac}\approx0.52$-$0.86$ eV. The authors determine the ionization energy of the 1A level of Cr from the electromodulation spectra. (15 refs.)

78.20L Magneto-optical effects

72772 Magnetic circular dichroism of colour centres in CaF_2:Na. J.L.Doualan, J.Margerie, F.Martin-Brunetiere (Lab. de Spectroscopie Atomique, Univ. de Caen, Caen, France), E.Rzepka.
J. Phys. Lett. (France), vol.44, no.10, p.L375-85 (15 May 1983).
The magnetic circular dichroism (MCD) of several centres in additively coloured CaF_2:Na has been measured as a function of temperature in the 1.65-195K range. The 612, 435 and 382-385 nm bands display significant paramagnetic MCD signals, which proves that they most probably arise from centres with an odd number of electrons. Thus 612 nm cannot be only a transition of the [1,0,0] oriented F_{2A} centre, as currently assumed. On the other hand, the 490 nm band only shows a diamagnetic MCD. The authors tentatively discuss some possible assignments for the chief absorption bands of colour centres in CaF_2:Na, but further work using complementary techniques is clearly necessary before one comes to a reliable conclusion. (13 refs.)

72773 Mixed rare-earth iron garnet for magneto-optic devices. O.Kamada, Y.Tsujimoto (Central Research Lab., Matsushita Electric Industrial Co. Ltd., Osaka, Japan).
Natl. Tech. Rep. (Japan), vol.29, no.1, p.163-9 (Feb. 1983). In Japanese.
Magneto-optic materials for optical current (magnetic field) sensors with high sensitivity and temperature stability are required. Based on a simple theoretical calculation, new mixed rare-earth garnet crystals, $(Tb_xY_{1-x})_3Fe_5O_{12}$, have been proposed and the crystal growth has been performed by a conventional flux method. By Verdet constant measurements of the crystals, it was found that crystals with a component of x=0.19 show a minimum temperature dependence of ±1% between 300~400K. This result agrees well with the theoretical estimation. The characteristics such as sensitivity and linearity of magneto-optical effect were measured. (5 refs.)

72774 Diffraction of light in magnetooptic media with a band domain structure. D.I.Sementsov, A.P.Gubarev.
Opt. & Spectrosc. (USA), vol.53, no.3, p.295-8 (Sept. 1982). Translation of: *Opt. & Spektrosk. (USSR)*, vol.53, no.3, p.501-6 (Sept. 1982). [received: May 1983]
Equations are obtained for magnetooptic diffraction (MOD) of light in media with a band domain structure, valid in the region $\sin\psi_0\ll1$ and $D\gg\lambda$. The character of the diffracted field is investigated for sinusoidal and binary distributions of the Faraday component of the magnetization in the two limiting cases of Raman-Nath and Bragg diffraction. It is shown that in the Raman-Nath region the results of solving the MOD equations found in the paper coincide with the results obtained within the framework of Fresnel-Kirchhoff theory for magnetooptic transparencies; for $\theta_F L\lesssim6°$ the efficiencies of Raman-Nath $\eta_{+1}{}^{RN}$ and Bragg $\eta_{-1}{}^{B}$ diffraction turn out to be identical. Because of the presence of a connection between the thickness and period of the domain structure of magnetic crystals the thin-layer condition $L\ll D^2/\lambda$ assumes the form $\Lambda\gg\lambda$, and Λ is the characteristic length of the material. (14 refs.)

72775 Magnetic bias field generator design for the measurement of magnetic garnet film properties using Faraday rotation. M.Kharboush, J.C.Cho (Electrical & Computer Engng. Dept., Louisiana State Univ., Baton Rouge, LA, USA).
IEEE SOUTHEASTCON '83 Conference Proceedings, Orlando, FL, USA, 11-14 April 1983 (New York, USA: IEEE 1983), p.36-40
A specially designed magnetic bias field generator was constructed. It provides uniform field perpendicular to the sample and varies from zero to 120 oersteds. Spacing is provided to allow a magnetic probe to be placed on the

magnetic garnet sample so that domain cutting experiments can be performed. Pictures were taken by use of Faraday rotation. (2 refs.)

78.20N Thermo-optical effects

72776 Thermoreflectance spectra of [1,6-di (*N*-carbazolyl)-2,4-hexadiyne] (DCHD) polymer single crystal. I.Davoli, S.Stizza, V.Prantera (Inst. of Phys., Univ. of Camerino, Camerino, Italy), R.Jankowiak, J.Kalinowski.
Acta Phys. Pol. A (Poland), vol.A63, no.4, p.571-4 (April 1983).
The results are described of thermoreflectance (TR) spectra measurements in DCHD polymer single crystal. The relation between reflectance (R) and TR spectra at room and low temperature is different than that found recently for PDA-TS polymer crystal. This is not understood but some possible reasons of the difference are suggested. (13 refs.)

72777 Thermoreflectance test of W, Mo, and paramagnetic Cr band structures. E.Colavita (Istituto di Fisica 'G. Marconi', Univ. degli Studi di Roma, Roma, Italy), A.Franciosi, C.Mariani, R.Rosei.
Phys. Rev. B (USA), vol.27, no.8, p.4684-93 (15 April 1983).
The authors present a systematic investigation of the electronic structure of W, Mo, and paramagnetic Cr. Thermoreflectance has been used to test the most recent band-structure calculations. Analysis of the systematic trends and improvement of the experimental method allowed them to identify a number of new critical-point and Fermi-surface transitions. An unambiguous interpretation is given for most optical-absorption features in the $0.5<h\nu<5.0$ eV photon-energy range. (34 refs.)

78.30 INFRARED AND RAMAN SPECTRA AND SCATTERING

72778 Infrared and Raman spectra and X-ray diffraction studies of solid lead(II) carbonates. M.H.Brooker (Dept. of Chem., Memorial Univ. of Newfoundland, St. John's, Newfoundland, Canada), S.Sunder, P.Taylor, V.J.Lopata.
Can. J. Chem. (Canada), vol.61, no.3, p.494-502 (March 1983).
Four basic lead carbonates were prepared and identified by X-ray powder diffractometry. These were hydrocerussite ($Pb_3(OH)_2(CO_3)_2$), plumbonacrite ($Pb_{10}O(OH)_6(CO_3)_6$), and the two adducts $MOH.2PbCO_3$ (M=Na, K). New diffraction data are presented for the latter two compounds; they both have primitive hexagonal lattices with two formula units per unit cell. The unit cell dimensions of the sodium and potassium compounds are $a=5.273\pm0.002$ Å, $c=13.448\pm0.005$ Å and $a=5.348\pm0.002$ Å, $c=13.990\pm0.005$ Å, respectively. Six possible space groups are discussed. Raman and infrared spectra are reported for all four compounds, and compared with those of cerussite ($PbCO_3$); assignment of the spectral features is discussed. Vibrational spectra of the two MOH adducts indicate that they are isostructural, and that the structure contains a well-defined lead sub-lattice, consistent with the X-ray data. The spectra of hydrocerussite and plumbonacrite indicate that lead is present as oxygen-bridged polymeric moieties in these solids. The carbonate ions occupy two and three independent sites in hydrocerussite and plumbonacrite, respectively. (43 refs.)

72779 Polarized Raman spectra of an oriented single crystal of barium nitrite monohydrate. O.P.Lambda, H.D.Bist, Y.S.Jain (Dept. of Phys., Indian Inst. of Technol., Kanpur, India).
Can. J. Chem. (Canada), vol.61, no.3, p.608-12 (March 1983).
The symmetries of the observed Raman lines in the 4000-30 cm^{-1} region in different orientations of a single crystal of $Ba(NO_2)_2.H_2O$ have been determined and the spectra have been analysed in terms of the phonons originating from the internal modes of the NO_2^- and H_2O groups and the external lattice modes. The longitudinal-optical and transverse-optical (LO-TO) splittings arising from the Coulomb forces in the crystal are reported for the first time. (15 refs.)

72780 Effects of underpotentially deposited Tl and Pb submonolayers on the surface-enhanced Raman scattering (SERS) from pyridine at Ag electrodes. T.Watanabe, N.Yanagihara, K.Honda (Dept. of Synthetic Chem., Faculty of Engng., Univ. of Tokyo, Hongo, Bunkyo-ku, Tokyo, Japan), B.Pettinger, L.Moerl.
Chem. Phys. Lett. (Netherlands), vol.96, no.6, p.649-55 (29 April 1983).
SERS from pyridine on an Ag electrode is almost completely quenched by underpotential deposition of Tl to a surface coverage of $\approx3\%$. Removal of Tl by anodic stripping does not restore the original SERS intensity. These results suggest that only a small fraction of adsorbed pyridine molecules is SERS active, and Tl is specifically deposited on such a SERS active site, which then undergoes irreversible destruction. Pb appears to be non-specifically deposited on the Ag surface, but exhibits a similar irreversible quenching of SERS. (21 refs.)

72781 Raman spectra and staging of intercalated graphite fibers. P.Kwizera, M.S.Dresselhaus (Center for Materials Sci. Engng., MIT, Cambridge, MA, USA), G.Dresselhaus.
Carbon (GB), vol.21, no.2, p.121-9 (1983).
Raman spectra of graphite fibers intercalated with K, Rb and Cs are reported. X-Ray diffraction is used to characterize the fibers with respect to staging. The authors report results mainly for GY70, a highly graphitic commercially available fiber, which is polyacrylonitrile (PAN) based, and some results on UC4104B, a pitch-based fiber. These two fibers have different structures; ideally the GY70 consists of graphite layers parallel to the fiber surface, while UC4104B has graphite planes perpendicular to the surface. X-ray diffraction, using the Debye-Scherrer method shows that these fibers stage, though compounds of mixed stages are generally obtained. The Raman results, which are sensitive to the staging within an optical skin depth, show for the alkali metal donor-intercalated fibers the 560 cm^{-1} line characteristic of stage 1 compounds, the E_{2g2} bounding layer mode characteristic of stage 2, as well as the interior and bounding layer splitting of the E_{2g2} mode, observed in high stage intercalated graphite. In addition, a Raman line near 1355 cm^{-1} is observed, characteristic of less ordered graphites. (23 refs.)

72782 A Raman spectroscopic study of the plastically crystalline state of organic compounds. S.Ganguly, H.R.Swamy, C.N.R.Rao (Solid State & Structural Chem. Unit., Indian Inst. of Sci., Bangalore, India).
J. Mol. Liq. (Netherlands), vol.25, no.2, p.139-47 (April 1983).
The depolarized and polarized components of internal Raman bands of succinonitrile, t-butyl chloride and t-butyl bromide in their plastic crystalline and liquid phases have been analyzed to obtain rotational and vibrational correlation functions. The rotational correlation times are continuous through the plastic-liquid transition and show an Arrhenius behaviour, from which activation energies for rotation have been calculated. Vibrational correlation times are nearly constant in the range of temperature investigated, except for a small change near the plastic-liquid phase transition temperature. (22 refs.)

72783 Consideration of the vibrational properties of germanium dichalcogenides on base of vibrational properties of GeX_4 (X=S,Se) tetrahedra. Z.V.Popovic (Inst. of Phys., Belgrade Univ., Beograd, Yugoslavia).
Fizika (Yugoslavia), vol.15, no.1, p.11-27 (Jan.-March 1983).
Vibrational properties of the single crystals GeS_2 and $GeSe_2$ have been analysed on the ground of the properties of their crystal structure (the basic building blocks in GeX_2 are GeX_4 tetrahedra, which are interconnected via common edge or a common corner). The authors have analysed the Raman and infrared spectra of an isolated GeS_4 tetrahedra, of single crystals $SnGeS_3$ and $PbGeS_3$, (whose GeS_4 tetrahedra are connected via common corners), then the Raman spectra of a Ge_2S_6 molecule, (built of two GeS_4 tetrahedra connected via common edge) and the Raman and infrared spectra of $a-$ of and $c-GeX_2$. It has been concluded that molecular vibrations of the variously connected GeX_4 tetrahedra are not only present in the single crystals GeS_2 and $GeSe_2$, too, but they also play a dominant role in vibrational properties of the germanium dichalcogenides. (26 refs.)

72784 The enhancement of Raman scattering, resonance Raman scattering, and fluorescence from molecules adsorbed on a rough silver surface. D.A.Weitz, S.Garoff (Exxon Res. & Engng. Co., Linden, NJ, USA), J.I.Gersten, A.Nitzan.
J. Chem. Phys. (USA), vol.78, no.9, p.5324-38 (1 May 1983).
The enhancements of normal Raman scattering, resonance Raman scattering, and fluorescence from molecular adsorbed on identical, well-characterized, silver-island films are reported. The enhancement arises from the electromagnetic interaction between the molecules and the electronic plasma resonance of the silver islands. A hierarchy of enhancement ratios is found, with typical values of 10^5 for RS, 10^3 for RRS and 10^{-1} to 10 for fluorescence, depending on the quantum yield of the molecular fluorescence. A model, developed on heuristic grounds and substantiated using the density matrix formalism, describes the light scattering processes and the effects of the plasma resonance. This model presents a unified picture of the surface-induced enhancement effects and is consistent with the experimental values. The comparison of all the forms of optical scattering leads to a complete determination of the role of the plasma resonances in the various portions of the scattering process. The excitation of the electronic plasma resonance results in an increased local field at the molecules leading to an increased excitation or absorption rate. Similarly, the excitation of the plasma resonance by the molecular emission dipole results in an increase in the radiative decay rate. However, the electromagnetic coupling of the molecule to the plasma resonance also adds an additional damping channel which can result in a reduction of the absorption or excitation rate as well as the emission yield. The resultant balance of these processes leads to the hierarchy in the measured enhancements. The hierarchy of enhancements is also shown to have important spectroscopic consequences. (39 refs.)

72785 Vibrational spectroscopy at high pressures. XL. A Raman study of manganese rhenium decacarbonyl. D.M.Adams (Dept. of Chem., Univ. of Leicester, Leicester, England), I.O.C.Ekejiuba.
J. Chem. Phys. (USA), vol.78, no.9, p.5408-12 (1 May 1983).
$MnRe(CO)_{10}$ undergoes two first-order phase transitions under hydrostatic pressures, at ~7 and ~13 kbar. The Raman spectra have been followed through these transitions and are interpreted in terms of a change of molecular geometry from staggered to eclipsed and back to staggered with increase of pressure. Comments are offered on the assignment of the vibrational spectra of this material. (16 refs.)

72786 An infrared absorption study of LTCVD silicon dioxide. C.Pavelescu, C.Cobianu (R&D Center for Semiconductors, Bucharest, Rumania), A.Vancu.
J. Electrochem. Soc. (USA), vol.130, no.4, p.975-7 (April 1983).
The absorption band at 880 cm^{-1} has been assigned to a Si-H bond in LTCVD silicon dioxide from silane and oxygen and it has been observed that the absorbance decreased with increasing deposition temperature. The authors investigate the behavior of the maximum absorption coefficient corresponding to this band with respect to CVD conditions in order to get an insight in the complex mechanism of silane oxidation. (11 refs.)

72787 Relaxation of electron-phonon system in optically excited quasi-1-D mixed valence crystal Wolffram's red salt. H.Tanino, K.Kobayashi (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1446-56 (April 1983).
Resonance Raman scattering and photo-luminescence in Wolffram's red salt are studied. Together with a Raman line and its overtones due to chlorine vibrations along the chain, a continuous, flat and Raman-like emission is observed in the emission spectra. The latter extends deeply into the band edge and is followed by a prominent luminescence band. These emission bands are explained in terms of the recombination during and after relaxation of a charge transfer excited state to the self-trapped state. Details of the relaxation process are discussed on the basis of experimental results on the spectral shapes, the intensities and the degree of polarisation of the spectra. These

experimental results provide the direct evidences for the characteristic relaxation process in self-trapping in a 1-d electron-phonon system.

72788 Enhanced Raman scattering by two-dimensional array of polarisable spheres. M.Inoue (Inst. of Appl. Phys., Univ. of Tsukuba, Ibaraki, Japan), K.Ohtaka.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1457-68 (April 1983).
Two-dimensional array of dielectric spheres gives rise to prominent peaks in the reflectivity spectrum of light, corresponding to the excitation of the localised modes. The authors demonstrate that these localised modes provide a new possibility of enhanced Raman scattering from a molecule adsorbed on arrayed dielectric spheres. It is found that the enhancement factor of order 10^4 is easily achieved, when the incidence and scattering angles of light are appropriate. By calculating the dispersion relation of the localised modes, the authors show that the excitation of them is clearly the origin of such a large enhancement. They also examine the enhanced Raman scattering for arrayed metallic spheres.

72789 Analysis of the soft mode behaviour in $Li_2Ge_7O_{15}$ in terms of a coupled-mode model. H.Orihara, M.Wada, Y.Ishibashi (Synthetic Crystal Res. Lab., Nagoya Univ., Nagoya, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1478-84 (April 1983).
On the basis of a coupled-mode model, the coupling between a soft mode and another optical mode (called a partner mode) in $Li_2Ge_7O_{15}$ observed by means of Raman scattering is analysed. The observed Raman profiles are satisfactorily fitted to the adopted model. From the results of the fitting it has turned out that both real and imaginary parts of the coupling constant are almost constant over the examined temperature range and the coupling between two modes is mainly through the nondissipative mechanism. High pressure Raman scattering measurements were performed. It was found that there is some difference between the temperature and pressure dependences of the behaviours of the coupled system.

72790 Raman spectra of potassium borogermanate glasses with high B_2O_3 contents. I.N.Chakraborty, R.A.Condrate,Sr. (New York State Coll. of Ceramics, Alfred Univ., Alfred, NY, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.C71-2 (April 1983).
Raman spectra were measured and analyzed for K_2O-B_2O_3-GeO_2 glasses containing 85% and 65% B_2O_3. Structural changes, e.g. in the coordination of boron (3 to 4) and germanium (4 to 6), were noted from the spectra when composition was varied. (9 refs.)

72791 Raman spectroscopy of calcium aluminate glasses and crystals. P.McMillan (Dept. of Chem., Arizona State Univ., Tempe, AZ, USA), B.Piriou.
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.221-42 (May 1983).
Solar furnace melting and fast-quench techniques have been used to prepare calcium aluminate glasses from 75 mol.% CaO to 82 mol.% Al_2O_3, which have been studied by Raman spectroscopy. The $CaAl_2O_4$ glass spectrum may be interpreted in terms of a fully-polymerized network of tetrahedral aluminate units, which is depolymerized on addition of CaO component analogous to binary silicate systems. The spectra of glasses with higher alumina content than $CaAl_2$-O_4 may not be simply interpreted and a structural model is proposed which would be consistent with the glass spectra and with observed crystal structures along the $CaAl_2O_4$-Al_2O_3 join. This model suggests formation of highly condensed aluminate tetrahedral on initial addition of alumina, with the appearance of aluminate polyhedra of higher average coordination at higher alumina content. Similar high coordination polyhedral are also suggested for a limited composition range along the CaO-$CaAl_2O_4$ joint. These interpretations are compared with the results of a previous study in the SiO_2-Al_2O_3 glass system. (51 refs.)

72792 Rare-earth titanates and stannates of pyrochlore structure; vibrational spectra and force fields. M.T.Vandenborre (Lab. de Spectrochimie du Solide, Univ. Pierre et Marie Curie, Paris, France), E.Husson, J.P.Chatry, D.Michel.
J. Raman Spectrosc. (GB), vol.14, no.2, p.63-71 (April 1983).
Infrared absorption and polarized Raman spectra of rare-earth titanates with the pyrochlore structure $Ln_2Ti_2O_7$ (Ln=Sm, Gd, Yb; Y) and $Ln_2Sn_2O_7$ (Ln=La, Sm, Gd, Yb, Lu; Y) have been recorded. A valence force field calculation clearly supports the assignment of the frequencies. A comparison of the results with those of homologous zirconates and hafnates is predicted. (20 refs.)

72793 Raman studies of vibrational and reorientational relaxation in rotator phase perfluorocyclohexane. R.T.Bailey, F.R.Cruickshank (Dept. of Pure & Appl. Chem., Univ. of Strathclyde, Glasgow, Scotland).
J. Raman Spectrosc. (GB), vol.14, no.2, p.72-6 (April 1983).
Vibrational and reorientational relaxation have been studied in rotator phase perfluorocyclohexane using Raman line-shape analysis. Two totally symmetric bands were investigated in the temperature range from 170 to 300K. The results were compared with the predictions of the Kubo stochastic line-shape theory. Activation enthalpies for molecular reorientation were consistent with previous NMR results. (21 refs.)

72794 Temperature dependence of the low frequency Raman scattering spectra in tetramethylammonium tetrachlorozincate. J.Henocque, J.L.Sauvajol, J.Lefebvre (Lab. de Dynamique des Cristaux Moleculaires, Univ. des Sci. et Tech. de Lille, Villeneuve d'Ascq, France), G.Marion.
J. Raman Spectrosc. (GB), vol.14, no.2, p.93-5 (April 1983).
The behaviour of some lattice modes in the Raman spectra (wavenumber shift range 0.50 cm^{-1}) has been investigated for $(N(CD_3)_4)_2ZnCl_4$ and $(N(CH_3)_4)_2\ ZnCl_4$ over the temperature range 183-523K. (6 refs.)

72795 Raman and infrared spectra of solid carbon diselenide. B.H.Torrie, B.Andrews, A.Anderson (Guelph-Waterloo Program for Graduate Work in Phys., Univ. of Waterloo, Waterloo, Ontario, Canada), B.M.Powell.
J. Raman Spectrosc. (GB), vol.14, no.2, p.96-8 (April 1983).
Raman and infrared spectra of polycrystalline samples of CSe_2 have been recorded at temperatures from 20-205K. A comparison with previous results for CS_2 shows that the spectra are consistent with the two substances having the same centrosymmetric orthorhombic structure. The observed spectra for CSe_2, in both the lattice and molecular regions, are in good agreement with group theoretical predictions based on this structure. There is only one solid phase over the range of temperatures examined. (12 refs.)

72796 The Raman spectra of manganese and zinc fluorotitanate hexahydrate systems. P.Choudhury, B.Ghosh (Saha Inst. of Nuclear Phys., Calcutta, India), G.S.Raghuvanshi, H.D.Bist.
J. Raman Spectrosc. (GB), vol.14, no.2, p.99-101 (April 1983).
Raman spectra of $ZnTiF_6.6H_2O$ and $MnTiF_6.6H_2O$ single crystals have been observed in different polarizations. The various mode frequencies have been identified by studying the spectra in solution and comparing the data with those on similar systems. (8 refs.)

72797 Magnetic electronic Raman optical activity of osmium (IV) hexabromide, iridium (IV) hexachloride and uranocene. L.D.Barron, J.Vrbancich (Chem. Dept., Univ. of Glasgow, Glasgow, Scotland).
J. Raman Spectrosc. (GB), vol.14, no.2, p.118-25 (April 1983).
Magnetic optical activity is reported in electronic resonance Raman transitions of $OsBr_6^{2-}$, $IrCl_6^{2-}$ and $U(C_8H_8)_2$ in solution. All the effects are observed in the form of couplets which originate in separate Raman transitions between magnetic components of the initial and final levels. These can give detailed information about the magnetic structure of the ground and low-lying electronic states, particularly the sign of the g-factor and the ordering of magnetic sub-states in general. For example, effects in the 466 cm^{-1} electronic Raman band of $U(C_8H_8)_2$ confirm that the $M_J=\pm 4$ level lies below the $M_J=\pm 3$ level. The authors also use the magnetic Raman optical activity to identify a very weak $U(C_8H_8)_2$ Raman band at 675 cm^{-1} with a vibrational-electronic combination transition. (27 refs.)

72798 Precision Raman investigation of the ν_1 mode of vibration of SO_4^{2-}, WO_4^{2-} and MoO_4^{2-} in aqueous solutions of different concentrations. K.J.Dean, G.R.Wilkinson (Wheatstone Phys. Lab., King's Coll., London, England).
J. Raman Spectrosc. (GB), vol.14, no.2, p.130-4 (April 1983).
The ν_1 vibrational Raman modes of the anions SO_4^{2-}, WO_4^{2-} and MoO_4^{2-} have been studied in aqueous solution with great precision, and the effect of different alkali metal cations (Li^+, Na^+, K^+, Rb^+ and Cs^+) carefully recorded as a function of concentration. The results show that the symmetric vibrational frequency of the anions is dependent on both the concentration and on the cation present in the solution. Precise values of the anion ν_1 frequencies were found at infinite dilution by extrapolation. These frequencies are: 980.75 ± 0.1 cm^{-1} for SO_4^{2-}, 931.1 ± 0.1 cm^{-1} for WO_4^{2-} and 986.1 ± 0.1 cm^{-1} for MoO_4^{2-}. When the alkali metal cations Li^+ or Na^+ were present in the solution, the anion ν_1 frequency was shifted to a higher value than the infinite dilution frequency, whereas, when K^+, Rb^+ or Cs^+ were present in the solution, the anion ν_1 frequency was decreased. The frequency shifts were also found to depend linearly on the square root of the solution concentration. The results also indicate that in ionic aqueous solutions the water molecule behaves as though it has a radius of 1.15 ± 0.01 Å and a polarizability of 0.39 ± 0.01 $Å^3$. An empirical relation between cation volume and polarizability has also been demonstrated. (20 refs.)

72799 An examination of the longitudinal acoustic mode of polyethylene crystals (Raman spectra). J.Runt, I.R.Harrison, W.D.Varnell, J.-I.Wang (Dept. of Materials Sci. & Engng., Pennsylvania State Univ., University Park, PA, USA).
J. Macromol. Sci. - Phys. (USA), vol.B22, no.2, p.197-212 (1983).
Chain lengths have been calculated from the peak positions of the longitudinal acoustic modes (LAM) of polyethylene single crystals grown at several different temperatures. The data are consistent with other experimental results when the crystalline elastic modulus is taken to be 3.6×10^{12} dyn/cm^2. However, this is true only if the vibrations of the crystalline chain segments are unaffected by the presence of folds and cilia on the crystal surface. The LAMs of several crystal preparations were also deconvoluted with the first-order LAM of $C_{94}H_{190}$ in order to remove instrumental broadening. The band shapes of the deconvoluted spectra are consistent with the idea that the LAM of polyethylene crystals is composed of two contributions: one due to chain stems in 110 sectors and a second due to chains in 200 sectors. (36 refs.)

72800 Addendum on infrared emission from n-InSb under crossed electric and magnetic fields. T.Morimoto, M.Chiba (Inst. of Atomic Energy, Kyoto Univ., Kyoto, Japan).
Phys. Lett. A (Netherlands), vol.95A, no.6, p.343-4 (9 May 1983).
The physical meaning of the infrared emission from InSb generated by the $\mathbf{J}\times\mathbf{H}$ force, especially the activity of the electron-hole system under high magnetic fields, and the relations with other works are discussed. (8 refs.)

72801 Raman scattering in GeS single crystals at low temperatures. V.Vorlicek, I.Gregora, D.Chvostova (Inst. of Phys., Czechoslovak Acad. of Sci., Prague, Czechoslovakia).
Phys. Status Solidi b (Germany), vol.116, no.2, p.639-43 (1 April 1983).
The Raman spectra of GeS single crystals are investigated in the temperature interval 20 to 300K. The possible origin of new features observed at low temperatures is discussed. A new assignment of the off-diagonal B_{1g} and B_{3g} modes is proposed. (11 refs.)

72802 Polarized Raman spectra of InS single crystal. K.Takarabe, K.Wakamura (Dept. of Natural Sci., Okayama Univ. of Sci., Okayama, Japan).
Phys. Status Solidi b (Germany), vol.116, no.2, p.K79-83 (1 April 1983).
The authors study the polarised Raman spectra of InS single crystals in order to study their crystal structure. They compare the Raman scattering from single crystals with that from twinned crystals. (7 refs.)

72803 Preparation and optical investigation of the $CdInGaS_4$ compound. K.Kambas (Lab. of Phys., Univ. Thessaloniki, Thessaloniki, Greece).
Phys. Status Solidi a (Germany), vol.76, no.2, p.735-41 (16 April 1983).
A method of preparation of the quaternary layer compound $CdInGaS_4$ is proposed to obtain single crystals of good quality for optical measurements. Far-infrared and Raman scattering measurements are performed at room temperature. These results are compared with available FIR and Raman data from the literature of $ZnIn_2S_4$ whose structure is accepted to be identical with that of $CdInGaS_4$. From electron microscopy diffraction patterns it is deduced that there is a superstructure due to a kind of ordering of Ga and In atoms within the layers and to this fact some extra frequencies in the FIR spectrum are attributed. Optical transmission and absorption measurements give an estimation of the optical energy gap (E_g=2.56 eV) at room temperature. (12 refs.)

72804 Local induced activity in resonant Raman scattering of GaP:N. M.P.Dos Santos, C.Hirlimann, M.Balkanski (Lab. de Phys. des Solides, Univ. Pierre et Marie Curie, Paris, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.108-9 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Resonant Raman scattering (RRS) in GaP:N at 5K is performed. By tuning the excitation photon energy through the 1s ground state energy of the exciton bound to NN_3, NN_4 and NN_7 pairs, in addition to the zone center Raman active to: 367 cm^{-1} and LO: 404 cm^{-1} modes, other peaks at 390 and 412 cm^{-1} appear corresponding to the high density of states of the TO (X) and LO (X). Due to the random distribution of N which breaks the momentum conservation these modes become first order Raman active. This result suggests that the intermediate state of the RRS process is now the X contribution of the N trapped exciton. (4 refs.)

72805 Momentum resolved polariton spectroscopy in CuBr in the presence of magnetic field. J.-C.Merle, A.Bivas, C.Wecker, J.-B.Grun (Lab. de Spectroscopie et d'Optique du Corps Solide, Univ. Louis Pasteur, Strasbourg, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.296-8 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The authors study the effect of a magnetic field H oriented along [$\bar{1}$10] on the hyper-Raman spectrum obtained in a backward scattering geometry from a [110] surface of a CuBr crystal. They investigate the energy $E(\underline{k},\underline{H})$ of various exciton-like polaritons for a fixed wave vector $\underline{k}$. The energies $E(\underline{k},\underline{H})$ being not symmetric with respect to $\underline{H}$, they conclude that the k-linear term plays an important role in the exciton dispersion. (9 refs.)

72806 Resonant Raman scattering in GaAlAs: first order active and disorder activated phonon lines. Theory of the IR dielectric susceptibility. B.Jusserand, R.Bonneville (CNET, Bagneaux, France).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.365-7 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Measurements of resonant first order Raman scattering on optical and disorder activated acoustical phonons in aluminium rich $Ga_{1-x}Al_xAs$ samples in the vicinity of the direct energy gap are reported. A calculation of the infrared dielectric response of $Ga_{1-x}Al_xAs$ using a shell-model and the coherent potential approximation accounts for the display of the optically active vibrations. (3 refs.)

72807 Resonance-Raman scattering and electron-phonon coupling in the cuprous halides. F.Meseguer, J.C.Merle, M.Cardona (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.374-6 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Resonance Raman scattering is investigated for the copper halides. Values of the Raman tensor, the electron-phonon deformation potential d_0, and the second harmonic generation d_{123} are obtained. (12 refs.)

72808 Vibrational spectra of some rhenium-apatites containing ReO_5-groups. E.J.Baran (Facultad de Ciencias Exactas, Univ. Nacional de La Plata, La Plata, Argentina), G.Baud, J.-P.Besse.
Spectrochim. Acta Part A (GB), vol.39A, no.5, p.383-6 (1983).
The vibrational spectra of a series of compounds of formula $Ba_{10}(ReO_5)_6X_2$ (with X=F, Cl, Br, I, $^1/_2$ CO_3^{2-}) belong to the apatite structural type, as well as that of the defective apatite $Ba_9(ReO_5)_6$, are reported and briefly discussed. The results show that the square pyramidal ReO_3 units present in these lattices possess a very characteristic and well defined pattern. (13 refs.)

72809 Infrared reflection spectra of gypsum. H.Takahashi, I.Maehara, N.Kaneko (Dept. of Chem., Waseda Univ., Tokyo, Japan).
Spectrochim. Acta Part A (GB), vol.39A, no.5, p.449-55 (1983).
Polarized IR reflection spectra of gypsum single crystals have been measured and analysed using the Kramers-Kronig relation. The transverse and longitudinal frequencies are obtained together with the optical and dielectric constants of the crystal. The librational bands of water of crystallization are identified based on the IR spectra of deuterated powders and low-temperature IR spectra. Polarized Raman spectra have also been measured, which agree well with those reported previously. (7 refs.)

72810 Raman scattering in quasi-one-dimensional $ZrTe_5$. I.Taguchi, A.Grisel, F.Levy (Inst. de Phys. Appliquee, EPF-Lausanne, Lausanne, Switzerland).
Solid State Commun. (USA), vol.46, no.4, p.299-303 (April 1983).
Raman scattering experiments on the compound $ZrTe_5$ isostructural with $HfTe_5$ have been performed at temperatures between 300-13K. The Raman spectra of $ZrTe_5$ resemble those of $HfTe_5$ excepting two high frequency modes which should include the most characteristic diatomic mode. In spite of structural similarity with the transition-metal trichalcogenides, the Raman scattering activity cannot be directly compared. These unexpected results and the usual temperature dependence of the Raman intensities suggest the possibility of a structural instability in $HfTe_5$ and/or $ZrTe_5$ in relation with the anomalies in the transport properties and in the X-ray forbidden reflections. (14 refs.)

72811 Photoacoustic and absorption spectra of UF_4. D.T.Hodul (Chem. Div., Argonne Nat. Lab., Argonne, IL, USA).
Spectrosc. Lett. (USA), vol.16, no.3, p.181-91 (1983).
The author has measured the photoacoustic spectrum of UF_4, extending the previously reported spectrum into the range of 800 nm to 2600 nm. Spectra at cryogenic temperatures were recorded for UF_4 in KBr pellets to assess the role of phonons in the broad spectral features of UF_4. A room temperature PAS spectrum of UO_2 has also been obtained for comparison. These data have been compared with those of Conway (1959) and Hecht and Gruber (1974), and the author has found qualitative agreement between the energies of these prior studies and those obtained in the study. The author interprets the broad spectral peaks observed in UF_4 compared to the narrow features seen in dilution studies as being derived from lower site symmetry of the U^{4+} species and/or uranium-uranium interactions. Shifts in peak maxima are attributed to differences in uranium-anion interaction. (16 refs.)

72812 Infrared observation of intrinsic modes on adsorbent surfaces by photothermal beam deflection spectroscopy. M.J.D.Low, A.G.Severdia, T.H.Arnold (Dept. of Chem., New York Univ., New York, NY, USA).
Spectrosc. Lett. (USA), vol.16, no.3, p.207-14 (1983).
In order to carry out IR work in the window region, very thin and fragile samples requiring fastidious and arduous preparation must be used and exacting measurements at very low IR intensities are required; suffice it to say that such work is extremely difficult with IR transmission methods. The authors propose and demonstrate an easier alternative approach. (6 refs.)

72813 Changes in the optical properties of oxygen in silicon as a result of heat treatment and irradiation. S.L.Olimpiev, V.A.Sutyagin (L.Ya. Karpov Sci.-Res. Physicochem. Inst., Obninsk, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1431-2 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2211-14 (Dec. 1982). [received: May 1983]
The authors identify all the absorption bands due to oxygen in Si and establish a relationship between the concentration of dissolved oxygen and the behavior of thermal and radiation defects. Irradiation was carried out by various fluxes of fast neutrons when the temperature of a sample did not exceed 50-60°C. Infrared spectra were recorded by a differential method at 80 and 300K. (9 refs.)

72814 Anomalies in the anisotropy of Raman scattering by polar vibrations in CdP_2 crystals. V.P.Grishchuk, A.V.Slobodyanyuk, Z.Z.Yanchuk (T.G. Shevchenko State Univ., Kiev, Ukrainian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1767-8 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3122-5 (Oct. 1982). [received: April 1983]
The authors have studied the Raman scattering due to polar vibrations of E symmetry in crystals of cadmium diphosphide, CdP_2, which belongs to the axial class 422 and which exhibits significant optical activity. They conclude that for a correct determination of the Raman tensor components in crystals it is necessary to take account of the polarization of the normal waves allowed by the crystal symmetry in the propagation directions of the incident and scattered light, both in the design of the experiment and in the analysis of the results. (12 refs.)

72815 The structure of Raman scattering spectrum for phianite of 0.9 ZrO_2-0.1 Y_2O_3 composition. N.D.Dovga, V.E.Pogorelov.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.530-4 (April 1983). In Russian.
The Raman scattering spectrum is investigated for a single crystal of phianite of 0.9 ZrO_2-0.1 Y_2O_3 composition. The spectrum complication is ascribed to ion vibrations in the structurally disordered oxygen sublattice with anion vacancies. Frequencies and symmetry of normal modes of vibrations are determined. 78.35 BRILLOUIN AND RAYLEIGH SCATTERING

72816 Quasi-elastic light scattering of Carnauba wax in the liquid phase: dynamics. I. L.Fonesca, G.A.Barbosa (Dept. de Fisica, Univ. Federal de Minas Gerais, Belo Horizonte, Brazil).
Appl. Opt. (USA), vol.22, no.9, p.1409-12 (1 May 1983).
Quasi-elastic light scattering of Carnauba wax in the liquid phase is done in a homodyne setup and is interpreted as due partially to polarized clusters. A dynamics model is proposed, and effective parameters are obtained in the 85-130°C temperature range. Some evidence exists that the local field seen by a polarized cluster is much higher than the applied static electric field. (9 refs.)

72817 Studies of EPR, spin, and phonon kinetics in parametic ionic crystals using Mandel'shtam-Brillouin and Raman scattering of light. S.A.Al'tshuler, B.I.Kochelayev, Yu.G.Nazarov, A.Kh.Khasanov (Kazan State Univ., Kazan, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.1-5 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.418-22 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
Studies the spectral and kinetic parameters of paramagnetic centers and of the phonons interacting with them in a CeMgN crystal, using Mandel'shtam-Brillouin scattering (MBS). Light scattered by Debye waves with frequencies in the region of the electron paramagnetic resonance (EPR) exhibit a frequency shift or even splitting of the fine-structure components of the Rayleigh line. This effect is due to a change in the velocity of sound, resulting from spin-phonon interactions and the onset of collective spin-phonon oscillations under certain definite conditions. Particular attention is devoted to the possibility of direct studies of nonequilibrium states of resonance phonons due to EPR saturation. Raman scattering of light which is of pure spin origin is also studied. In this case, the initial and final states involved in the Raman transition differ by the magnetic spin quantum number. Such transitions are due to indirect spin-photon coupling involving electric dipole and spin-orbital interactions. (17 refs.)

72818 Brillouin scattering study of the anisotropic relaxation of the polarisation fluctuation in ferroelectric TGS. Y.Tsujimi (Hokkaido Univ. of Education, Hakodate, Japan), T.Yagi, I.Tatsuzaki.
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1469-77 (April 1983).
The polarisation relaxation phenomena in the uniaxial ferroelectric TGS have been studied by the observation of the angular dependence of the Brillouin scattering spectra. Both the frequency shift and the full width of the Brillouin satellite show remarkable anisotropic anomalies most strongly at 44.94°C below the transition temperature $T_c=48.86°C$. The experimental result is successfully interpreted from the viewpoint of the depolarisation effect on the polarisation fluctuation. The effect is characterised by the anisotropic relaxation time with only two parameters; a relaxation time τ_0 for a transverse polarisation fluctuation and a generalised Lorentz factor L. The values $\tau_0=(0.93\pm0.09)\times10^{-11}$ sec and $L\simeq0.41$ give a good description of the experimental result. (34 refs.)

72819 Light scattering by decorated dislocations in alkali halide crystals. R.Kesavamoorthy, A.K.Arora (Materials Sci. Lab., Reactor Res. Centre, Kalpakkam, India).
J. Phys. C (GB), vol.16, no.13, p.2611-18 (10 May 1983).
The light scattering width of a dislocation decorated with lattice vacancies and impurities in doped alkali halide crystals is calculated. The contributions of the strain fields of dislocation and point defects to the change in dielectric constant are also considered. The calculations show that the decoration does not significantly change the light scattering from dislocations and it is the strain field of the dislocation that contributes most to the light scattering. Recent light scattering data and their interpretations are discussed in the light of the results of the present calculation. (10 refs.)

72820 Brillouin scattering in thin deposited polymer films. R.Zamoni, J.de Valera, G.I.Stegeman, J.F.Rabolt (IBM Res., San Jose, CA, USA).
J. Polym. Sci. Polym. Lett. Ed. (USA), vol.21, no.4, p.253-6 (April 1983).
Brillouin scattering has been proven over the last decade to be a valuable tool for studying the elastic and elasticity-related properties to bulk polymers, i.e. samples of millimeter dimensions. Recently, Dil et al. (1981), observed Lamb waves in submicron polycarbonate films deposited on Pyrex using a tandem multipass Fabry-Perot interferometer. However, it is difficult to deduce the longitudinal wave velocity from Lamb wave velocities which are determined largely by the shear elastic constant of the film. The authors report a unique scattering geometry based on optical guided waves which allowed them to measure longitudinal wave velocities in 1-μm-thick poly(methyl methacrylate) (PMMA), poly(vinyl alcohol) (PVA), and polystyrene (PS) films. (16 refs.)

72821 Brillouin scattering from amorphous polymers at low temperatures. M.Schmidt (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany), R.Vacher, J.Pelous, S.Hunklinger.
J. Phys. Colloq. (France), vol.43, no.C-9, p.501-4 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
For three different polymers (polymethylmethacrylate (PMMA), polystyrene (PS), and polycarbonate (PC)) sound velocity and attenuation of 18 GHz longitudinal phonons were measured in the temperature range from 0.3K to 20K by means of high resolution Brillouin spectroscopy. At the lowest temperatures from 0.3K to 3K all samples showed the characteristic low temperature behaviour of inorganic glasses, i.e. a logarithmic increase of the sound velocity and a decrease of the resonant absorption due to the interaction of phonons with two-level-systems. At higher temperatures (5K to 20K) for all samples, the absorption rises linearly with temperature whereas the sound velocity decreases proportional to T. This behaviour can be related to a thermally activated process. Data are only presented for PMMA as a typical example. (7 refs.)

72822 Light scattering from acoustic and low-frequency vibrational modes in borate glasses. J.Lorosch, M.Couzi, J.Pelous, R.Vacher, A.Levasseur (Lab. de Spectroscopie Infrarouge, Univ. de Bordeaux I, Talence, France).
J. Phys. Colloq. (France), vol.43, no.C-9, p.541-3 (Dec. 1982). [received: April 1983] (Physics of Non Crystalline Solids. Proceedings of the 5th International Conference, Montpellier, France, 5-9 July 1982).
Brillouin and low frequency Raman scattering experiments have been performed on series of B_2O_3-xM_2O glasses where M=Li, Na, K, Rb, Cs, T*l*. The concentration and composition dependences of the velocity and attenuation of longitudinal and transversal acoustic waves have been measured, as well as those of the Raman 'boson' peak. The composition and concentration dependence of the acoustic velocity seems to result from two competitive effects: the first one is related to the transition of boron atoms from three to four coordination with increasing x and the second one to the structural changes connected to the sterical hindrance of the M^+ cations. The maximum frequency of the boson peak has a behaviour similar to that of sound velocity. This similarity can be understood on the basis of the continuum theory of low-frequency Raman spectrum. (8 refs.)

72823 Measurements of visual light scattering in glass electrets. E.Rysiakiewcz-Pasek (Inst. of Phys. Tech. Univ. of Wroclaw, Wroclaw, Poland).
Opt. Appl. (Poland), vol.12, no.3-4, p.445-9 (1982).
Presents the results of an examination of visual light scattering in glass samples to which an external electric field is applied. It has been stated that in electret samples the scattering was greater than in samples treated only thermally. On the basis of the light scattering measurements a model of charge distribution in glass electrets is suggested. The optical glasses of the crown group BK-7 and BK-107 were used in the examinations. They are of the following chemical composition: BK-7-68.6% SiO_2, 11.0% B_2O_3, 11.0% Na_2O, 6.0% K_2O, 2.4% BaO, 1.0% As_2O_3, while BK-107 being of the same composition contains additionally 0.2 per cent by weight of CeO_2. (8 refs.)

72824 Phonon selectivity in resonant Brillouin scattering (RBS) from multi-component polaritons. M.Yamane, K.Cho (Faculty of Engng. Sci., Osaka Univ., Toyonaka, Japan).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.377-9 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Phonon selectivity in resonant Brillouin scattering (RBS) from multi-component polaritons in the back scattering geometry is discussed for the deformation and piezoelectric potential interactions in the long wavelength limit. An explicit calculation of RBS intensities is also presented for the parallel ($e_i//e_s$) and cross ($e_i\perp e_s$) polarized back scatterings from CuBr[$Z_{1,2}$] for k//[111], with assumed ABCs in a generalized Pekar form. (17 refs.)

72825 Resonant Brillouin scattering in GaAs—linewidth measurements and the effect of stress. R.Sooryakumar, P.E.Simmonds (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.380-2 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Five pass Fabry Perot interferometry is used to study the linewidths of exciton-polaritons resonant Brillouin scattered by phonons in GaAs. Both inter- and intra branch peaks are measured. An interpretation of the results in terms of excitons with an energy independent damping is shown to be inadequate for GaAs. The effect of stress is investigated and the observed decrease in masses of the stress decoupled excitons is in agreement with calculations based on experimental band parameters. (8 refs.)

72826 Diffraction properties of the classical superlattice of nonequilibrium carriers in a small modulation-amplitude semiconductor. L.A.Prokhnitskii.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.525-30 (April 1983). In Russian.
Light diffraction by a semiconductor superlattice is considered in a heating electric field. The superlattice is formed by a periodically modulated electron density. The heating electric field is shown to significantly influence the diffracted wave intensity. This phenomenon can be used in principle for controlling the energy redistribution between the main and diffracted waves in transmitted light. (13 refs.)

78.40 VISIBLE AND ULTRAVIOLET SPECTRA

72827 The oblique incidence *P*-wave reflection spectra of the cleavage surfaces of $MgCl_2$ crystals. S.Kinno, R.Onaka (Inst. of Appl. Phys., Univ. of Tsukuba, Ibaraki, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1485-8 (April 1983).
The reflection spectra of $MgCl_2$ single crystals having a uniaxial layer structure are studied with *p*-polarised light obliquely incident upon the cleavage surfaces. From the comparison between the experimental facts obtained from the reflection spectra and the electronic band structure calculated theoretically, it is confirmed that the top of the valence band belongs to Γ_3^- and a Γ_2^- state lies just below this.

72828 Blue shifts of the optical transitions in MnO below T_N. M.S.Seehra, R.D.Groves (Phys. Dept., West Virginia Univ., Morgantown, WV, USA).
J. Phys. C (GB), vol.16, no.13, p.L411-16 (10 May 1983).
The temperature dependence of the optical transitions (A, B and C bands) in MnO was measured between 27 and 295K, with particular attention to the region near $T_N\simeq118K$. All three bands undergo blue shifts below T_N, with the total shift $\Delta E\simeq1\%$ between T_N and 27K. Using the Penn model for dielectric constant, it is argued that the observation of $\sqrt{\Delta E}$ being proportional to σ (order parameter) for the A and B band is consistent with the dielectric anomaly reported recently in MnO below T_N. (15 refs.)

72829 Excitonic effects in the interband spectra of metals. A.B.Kunz, C.P.Flynn (Dept. of Phys., Univ. of Illinois, Urbana, IL, USA).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1524-7 (9 May 1983).
It is shown that Coulomb interactions among quasiparticles can play a determining role in the interband optical transitions of polyvalent metals. Explicit calculations for Mg metal made by configuration-interaction methods greatly improve upon the results of single-particle self-consistent-field calculations. (12 refs.)

72830 Reflectance and UPS studies of band structures and final state interactions of low-spin pyrites. S.Suga, M.Taniguchi, S.Shin, M.Seki, S.Shibuya (Synchrotron Radiation Lab., Univ. of Tokyo, Tokyo, Japan), K.Sato, T.Yamaguchi.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.353-5 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Reflectance spectra of FeS_2 and NiS_2 have been measured with synchrotron radiation from 4 to 30 eV. The intensity decrease of the p(valence)$\rightarrow$p*+dγ

(conduction band) excitation from FeS_2 to NiS_2 is a characteristic feature of the low-spin configuration of the 3d electrons in pyrites. Photoelectron partial yield spectrum of FeS_2 has shown conspicuous multiplet structures in the region of the 3p core ($M_{2,3}$) excitation, which are quantitatively analyzed by a newly developed theory based on a localized model. The reduction factors κ_F and κ_G of the Coulomb and exchange interactions between the core p hole and the d electron are evaluated as 0.5 and 0.4, in agreement with the large covalency and itinerant nature of the d electrons in pyrites. (6 refs.)

72831 Optical determination of exciton sizes in semiconductors. S.M.Kelso (Xerox Palo Alto Res. Center, Palo Alto, CA, USA), D.E.Aspnes, C.G.Olson, D.W.Lynch.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.362-4 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
The authors have studied the gradual disappearance of Ga3d core-exciton-related features in energy derivative reflectance spectra of GaAs crystals ion-implanted to increasing fluences. The data yield radii $r_L=23$ Å and $r_X=28$ Å for the L and X excitons. In addition, a lineshape fit for unimplanted GaAs yields core exciton binding energies $E_L=0.172$ eV and $E_X=0.129$ eV. These radii and binding energies are not related through an effective mass approximation description of the core exciton. (6 refs.)

72832 Strong electron-phonon interaction effects in modulated transient reflectance spectra of $Ga_{50}In_{50}P$. S.Sugai, J.H.Harris, A.V.Nurmikko (Div. of Engng., Brown Univ., Providence, RI, USA).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.368-70 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Time-resolved modulated reflection spectrum near the fundamental edge of MBE-grown direct-gap $Ga_xIn_{1-x}P$ ($x=0.5$) has been studied by using sensitive picosecond excite-probe methods. The spectrum at 77K shows considerable structure in comparison with steady-state photoluminescence data. In particular, a strong optical phonon coupling effect has been observed in the transient spectra, suggestive of impurity intermediated bound polaron behavior. (11 refs.)

72833 Reflectance spectra and dielectric functions for Ag in the region of interband transitions. G.Leveque (Dept. of Phys., Iowa State Univ., Ames, IA, USA), C.G.Olson, D.W.Lynch.
Phys. Rev. B (USA), vol.27, no.8, p.4654-60 (15 April 1983).
New measurements have been made of the reflectances of single crystals of Ag and of Ag films in the (3.5-30)-eV range. The data were analyzed with the Kramers-Kronig method and the resultant dielectric functions were compared with those in the literature and with recent applications. The authors find all structures previously seen, and a new weak peak at 11.5 eV. Their magnitudes for ϵ_2 are in considerably better agreement with those of the calculated spectra than are those in the literature. Second-derivative spectra of the absorption coefficient have been calculated and compared with previously measured thermotransmission spectra, showing the latter to arise primarily by temperature-dependent broadening. (21 refs.)

72834 Study of the $[Co(CS_3)_3]^{3-}$ anion by UV-visible spectroscopy. J.N.Pons, J.Roger, M.Stern (Lab. de Chimie II, Univ. Pierre et Marie Curie, Paris, France).
Rev. Chim. Miner. (France), vol.20, no.1, p.118-22 (1983). In French.
Solution spectra of anion $[Co(CS_3)_3]^{3-}$ containing compounds do not show the predictable number of bands, and their shape depends on the nature of the solvent. With solids, especially $[(CH_3)_4N]_3[Co(CS_3)_3]$, the spectra are well defined, give access to the Racah parameters and locate the CS_3 ligand in a spectrochemical series among the sulfur ligands with the strongest field; its nephelauxetic effect however, although important, is weaker. (11 refs.)

72835 Metastable deexcitation spectroscopy and ultraviolet photoemission spectroscopy on electropolymerised polyacrylonitrile layer. C.Reynaud (Service de Phys. des Atomes et des Surfaces, CENS, Gif-sur-Yvette, France), C.Boiziau, G.Lecayon, C.Le Gressus.
Scanning Electron Microsc. (USA), pt.3, p.961-6 (1982).
Studies polyacrylonitrile (PAN) which has interesting properties because of the presence of the polar nitril group. Heat treatment at 200°C produces a reticulation of the layer. This important structural transformation influences the electrical conduction as well as electronic spectra of the layer. The PAN layer behaves as a conductor above 100°C but undergoes sample charging phenomena below. The electrical properties are compatible with the phonon assisted hopping model. The spectra recorded for untreated and reticulated samples are in good agreement with previous molecular orbital calculations. This suggests that surface acrylonitrile molecules are weakly perturbed. (13 refs.)

78.45 STIMULATED EMISSION

(see also 42.65C in nonlinear optics)

72836 Control of carrier concentration by stimulated emission in highly excited direct gap semiconductors. V.D.Egorov, G.O.Muller, H.H.Weber (Zentralinst. für Elektronenphys., Akad. der Wissenschaften, Berlin, Germany), M.A.Jacobson, A.F.Dite.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.342-4 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Stimulated recombination may result in orders of magnitude reductions of lifetime of photo-excited carriers depending on the length over which optical amplification of (spontaneous) emission can occur. This effect has been verified in the excitation spot dependence of photoconductivity in CdS, in agreement with model calculations. (8 refs.)

78.50 IMPURITY AND DEFECT ABSORPTION IN SOLIDS

72837 The F centre near a charged dislocation. J.L.Marin-Flores, R.Rodriguez-Mijangos, C.Ruiz-Mejia (Escuela de Altos Estudios, Univ. de Sonora, Sonora, Mexico).
J. Phys. Soc. Jpn. (Japan), vol.52, no.4, p.1489-97 (April 1983).
The effect of the electric field due to a charged dislocation on the F Centre absorption spectrum is studied by the method of moments for an NaCl crystal. The elastic interaction of the centre with the dislocation strain field is also considered. The authors have calculated for these perturbations the fractional change in the peak height of the F band. Calculations suggest that this quantity can be measured experimentally and also that the effect of the electric field of a charged dislocation on the F centre spectrum is stronger than that of an F centre in a uniform field of the same strength. (29 refs.)

72838 Effect of aluminum content on infrared characteristics of BaF_2/ThF_4-containing glasses. B.Bendow, P.K.Banerjee, M.G.Drexhage, O.H.El-Bayoumi (Solid State Sci. Div., Rome Air Dev. Center, Hanscom AFB, MA, USA), S.S.Mitra, C.T.Moynihan, D.Gavin, G.Fonteneau, J.Lucas, M.Poulain.
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.C64-6 (April 1983).
The incorporation of large amounts of aluminum substantially alters the IR characteristics of BaF_2/ThF_4-based glasses. In particular, a distinct peak associated with aluminum is observed in the fundamental reflectivity spectrum at ≈ 625 cm^{-1}, with a concomitant shift of the IR absorption edge to higher frequencies. Although beneficial for glass formation, the addition of aluminum has a deleterious effect on the IR transparency range of heavy-metal fluoride glasses. (15 refs.)

72839 New absorption band in the near IR assigned to a bound triplet state of the *F′* in NaI. G.Baldacchini, G.P.Gallerano (ENEA, Frascati, Italy), U.M.Grassano, F.Luty.
Lett. Nuovo Cimento (Italy), vol.36, ser.2, no.15, p.495-8 (9 April 1983).
The $F \rightarrow F'$ optical conversion in NaI is reduced by an external magnetic field, but not completely suppressed. In order to explain such unexpected result both a spin mixing in the optical cycle of the *F*-centre and the existence of a bound triplet state of the *F′*-centre have been considered. Absorption measurements have disclosed a new band at 1.4 eV whose properties are those expected in a transition from a triplet state. Moreover, its absorption intensity is in complete agreement with that calculated from the incomplete quenching of the $F \rightarrow F'$ conversion in a magnetic field. (8 refs.)

72840 A new conversion coefficient for oxygen content. Determination in Si by IR absorption. T.Iizuka, T.Arai, T.Nozaki, M.Tajima, N.Inoue, M.Watanabe, S.-I.Takasu.
Oyo Buturi (Japan), vol.51, no.11, p.1269-70 (Nov. 1982). In Japanese. [received: March 1983]
Dislocation free CZ silicon crystals of 2,1 and 0.5 mm size with polished surfaces were used. Oxygen was determined by the IR absorption in Si method using a zero oxygen reference. The results were plotted and a new conversion coefficient calculated after statistical analysis of the results. (6 refs.) *M.O.*

72841 Infrared absorption due to pair modes of the NO_2^- ions doped in KI single crystals. S.S.Khatri, A.L.Verma (Dept. of Phys., North-Eastern Hill Univ., Shillong, India).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.191-3 (25 April 1983).
Several extra bands in the vicinity of the antisymmetric stretching vibration of the NO_2^- ion doped in KI single crystals containing $\approx 10^{19}$ NO_2^- ions per cm^3 have been observed in high resolution infrared studies at 1.7K. These extra features are believed to arise from interactions between the induced dipole moments during ν_3 vibrations of the nearby nitrite ion pairs. (6 refs.)

72842 Spectroscopic studies of 450°C thermal donors in silicon. B.Pajot (Groupe de Phys. des Solides de l'Ecole Normale Superieure, Univ. Paris VII, Paris, France), H.Compain, J.Lerouille, B.Clerjaud.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.110-12 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Spectroscopic experiments (EPR and IR) on the 450°C thermal donors (TD) in oxygen rich silicon confirm that they are double donors with an effective mass character and a ladder of ionization energies. Nine distinct centres are identified. The experimental results can be explained qualitatively by the double donor character of a Si+O interstitial molecule which can form donor complexes first with interstitial oxygen and then with increasingly bigger neutral Si.O complexes. (10 refs.)

78.55 PHOTOLUMINESCENCE

72843 Effect of spin polarization, spin reorientation, and spin-lattice relaxation on the luminescence emitted by alkali-halide crystals at very low temperatures. G.Liid'ya (Phys. Inst., Acad. of Sci., Estonian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.11-14 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.429-32 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
The spin polarization of electron and hole trapping centers in alkali-halide crystals in a magnetic field can be investigated by examining the luminescence emitted when the electron centers recombine with hole centers. The quenching of recombinational tunnel luminescence of alkali-halide crystals (AHC) in a magnetic field, has been used as a method for the optical detection of EPR in dye centers. In this work, the authors consider photostimulated luminescence emitted after the excitation or ionization of electron centers by light. The hole centers will be taken to be V_k centers (self-localized holes) produced by X-rays at $T \approx 100K$. (16 refs.)

72844 Optical alignment in semiconductors. M.I.D'yakonov, I.A.Merkulov, V.I.Perel (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.3, p.60-4 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.3, p.482-6 (1982). [received: April 1983] (Proceedings of the All-Union Seminar on the Optical Detection of Magnetic Resonances in Solids, Leningrad, USSR, 6-8 April 1981).
A brief review is given of effects occurring during the optical alignment of carrier spins in a semiconductor. Examples are given of the application of the optical alignment method to the investigation of the band structure of semiconducting materials, relaxation processes, and the interaction between electrons and the nuclear spin system in the lattice of a semiconductor. (16 refs.)

72845 Effects in the optical and electrical properties of CdS crystals from the accumulation of structural defects under laser irradiation. M.S.Brodin, N.A.Davydova, I.Yu.Shablii (Phys. Inst., Acad. of Sci., Ukrainian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.25-30 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1037-43 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
Measurements have been made on the recombination spectra of CdS crystals previously exposed to ruby-laser pulses, and some electrical characteristics have also been measured, which has shown that structural defects mainly of donor type are produced, whose concentration increases with the pulse power and with the number of pulses. (13 refs.)

72846 Dependence of the gap on hydrogen content in a-Si:H. Chen Zhiming, Chen Tingjie, Kong Guanglin, Lin Lanying (Inst. of Semiconductors, Acad. Sinica, Shanghai, China).
Chin. Phys. (USA), vol.3, no.1, p.180-7 (Jan.-March 1983). [received: May 1983]
The optical gaps and the photoluminescence spectra of a-Si:H films prepared under different deposition conditions and their changes in annealing are measured. The results, combining the measurements of the infrared absorption spectra, show that both the pseudogap between the two band tails and the mobility gap of a-SiH broaden as the hydrogen content increases. Dehydrogenation makes the pseudogap and the mobility gap narrow, and increases dangling bonds, in a random network, which are responsible for the deep donor state at 1.20 eV below the conduction band tail and the corresponding defect photoluminescence. (12 refs.)

72847 Steady-state delayed fluorescence signals in Ronchi ruling experiments: theory of coherence effects. V.M.Kenkre, A.Fort, V.Ern (Lab. de Spectroscopie et d'Optique du Corps Solide, Univ. Louis Pasteur, Strasbourg, France).
Chem. Phys. Lett. (Netherlands), vol.96, no.6, p.658-63 (29 April 1983).
Effects of coherence in triplet exciton transport are analyzed in the context of measurements of steady-state delayed fluorescence signals from molecular crystals excited through Ronchi rulings. (19 refs.)

72848 Special features of photoluminescence of GaAs films produced by molecular-beam epitaxy. V.I.Vovnenko, V.S.Ershov, N.S.Zayats, D.V.Korbutyak, E.G.Lashkevich, K.Lukat, Yu.G.Sadof'ev.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.11-19 (1982). In Russian.
The photoluminescence at 77K and 4.2K of GaAs films produced by molecular beam epitaxy is studied. The basic uncontrolled impurities in the films studied are found to be Mn, Ge, Si, C and Cr and the basic sources of pollution of the molecular beam epitaxy films are shown to be the stainless steel used to manufacture a number of items of production equipment and also gallium. When metallic As is used as the arsenic source, the films produced are purer and more perfect in composition than the films grown from polycrystalline gallium arsenide. The results of investigations into the phonon repetitions of the band with $h\nu_m = 1.404$ eV, its halfwidth and the Franck-Condon shift for different molecular beam epitaxy films indicate the presence of an extremely high degree of electron-phonon interaction for the corresponding Mn-centre. These results may also be used to draw conclusions about the degree of perfection of the films produced. (18 refs.) *L.M.H.*

72849 An electrodynamic theory of the nonadiabatic effects in rate processes for molecules adsorbed on metals. H.Metiu (Dept. of Chem., Univ. of California, Santa Barbara, CA, USA).
Isr. J. Chem. (Israel), vol.22, no.4, p.329-38 (1982).
The author presents a theory which computes the role of the electronic excitations in a metal substrate in dynamic processes involving adsorbed molecules. He uses a model in which the molecular skeleton has effective charges whose magnitude and position varies when the nuclei of the molecule move. These moving charges couple to the electrons in the metal and excite them; as a result the molecule loses energy. The rate of such energy loss affects the vibrational line-width and the fluorescence lifetime of the molecule, the van der Waals interaction between adsorbed molecules and the motion of the molecule at the surface. He shows how these effects can be discussed in a unified way in terms of an electromagnetic theory. He emphasizes that for obtaining reasonable numerical results one must replace phenomenological Maxwell equations with a microscopic theory that takes into account the non-locality of the electron response to moving charges and the continuous nature of the interface. (42 refs.)

72850 Photoluminescence of iron-doped $KMgF_3$. A.Poirier, D.Walsh (Rutherford Phys. Building, McGill Univ., Montreal, Quebec, Canada).
J. Phys. C (GB), vol.16, no.13, p.2619-24 (10 May 1983).
Uniaxial stress applied to $KMgF_3$:Fe samples reveals that the ground state of the ion, which emits photoluminescence peaks in the 14000 cm^{-1} region at low temperature (2K), is a singlet orbital state. X-ray irradiation and heat treatment in O_2 and H_2 atmospheres together with high-temperature spectra (30K) of the $KMgF_3$:Fe samples show that the most probable ion is Fe^{3+}, the observed transitions being $^4T_1 \rightarrow {}^6A_1$. (24 refs.)

72851 Luminescence of Eu^{3+} and Tb^{3+} ions adsorbed on hydrated layer-lattice silicate surfaces. F.Bergaya, H.van Damme (Centre de Recherche sur les Solides a Organisation Cristalline Imparfaite, CNRS, Orleans, France).
J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.4, p.505-18 (April 1983).
The luminescence of Eu^{3+} and Tb^{3+} ions which have been cation exchanged on montmorillonite and hectorite clays has been monitored as a function of the amount of water co-adsorbed on the clay. The luminescence intensity of the montmorillonite samples was negligible, probably due to energy transfer to the Fe^{3+} ions of the montmorillonite lattice. With hectorite, the luminescence intensity displayed complex behaviour with a dramatic increase for some hydration states, which was qualitatively rationalised in terms of the rare-earth-clay interactions on the one hand and the rare-earth-water interactions on the other. (37 refs.)

72852 Low temperature photoluminescence of lightly Si-doped and undoped MBE GaAs. F.Briones, D.M.Collins (Solid State Lab., Hewlett-Packard Labs., Palo Alto, CA, USA).
J. Electron. Mater. (USA), vol.11, no.4, p.847-66 (July 1982). [received: Nov. 1982]
A semiquantitative low temperature photoluminescence technique has been used to estimate the residual carbon concentration in MBE GaAs to be $\sim 2 \times 10^{14}$ cm^{-3}. This value agrees well with the total compensating acceptor concentration calculated from electrical measurements and thus confirms that carbon is the dominant residual acceptor in MBE GaAs. In high purity MBE GaAs films grown at substrate temperatures between 545°C and 625°C a band of at least nine luminescence peaks is observed in the 1.471 eV to 1.491 eV spectral region. These peaks can be correlated with the most prominent 'defect-induced' bound excitation peaks in the 1.504 eV to 1.511 eV spectral region and anir transition energies follow the empirical relation. (16 refs.)

72853 Optical spectra of pairs of Ni^{2+} ions in MgO. G.A.Grinvald, N.A.Mironova.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.22-7 (1983). In Russian.
Fine structure of the $^3A_{2g} \rightleftarrows {}^3T_{2g}$ band of Ni^{2+} (5 at.%) in MgO has been studied. Apart from $^3A_{2g} \rightleftarrows E(^3T_{2g})$ zero-phonon line of the isolated ion, three lines are associated with the nickel pair (probably nearest neighbour), whereas one line is connected with another Ni^{2+} cluster. The positions of two components of both the $E(^3T_{2g})$; $^3A_{2g}$ and the $^3A_{2g}$; $^3A_{2g}$ manifolds of the Ni^{2+} pair are determined. Temperature dependence of relative intensities of luminescence from isolated ions, their pairs and 'clusters' can be explained by energy transfer between these centres. (15 refs.)

72854 Luminescence of Ni^{+2} in $Ni_cMg_{1-c}O$ single crystals. G.A.Grinvald, N.A.Mironova.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.28-34 (1983). In Russian.
The fine structure of the $^3A_{2g} \rightleftarrows {}^3T_{2g}$ band of Ni^{2+} in $Ni_cMg_{1-c}O$ single crystals, where c varies from 0.01 to 1.00, has been studied. It is found that for $c \geq 0.05$ the best part of the luminescence intensity is associated with Ni^{2+} centres, which form traps of electron excitation. The luminescence intensities of such Ni^{2+} centres vary like $e^{\Delta/kT}$, where Δ is the depth of the trap. (9 refs.)

72855 Fluorescence spectra and energy migration behavior of *o*-terphenyl single crystal and glassy solid. T.Onaka-Ito, Y.Maruyama (Dept. of Chem., Ochanomizu Univ., Tokyo, Japan).
Mol. Cryst. & Liq. Cryst. (GB), vol.91, no.3-4, p.187-96 (1983).
Fluorescence spectra of very pure *o*-terphenyl single crystal and glassy solid were observed and their origins were assigned to intramolecular excimer states. For the anthracene-doped *o*-terphenyl solids, the concentration dependence and/or time evolution behavior of the fluorescence spectra showed that the energy transfer really occurs even in the glassy solid and its rate is of nearly the same order of magnitude as in the crystal. (9 refs.)

72856 Recent progress in characterisation techniques. Development and standardisation of new techniques. M.Tajima (Electrotech. Lab., Ibaraki, Japan).
Oyo Buturi (Japan), vol.51, no.11, p.1255-61 (Nov. 1982). In Japanese. [received: March 1983]
IR absorption is central to characterisation methods. Two photoluminescence methods developed by the author are described. Using them the quantitative measurement of dopant levels in silicon crystals is possible. Further development of the techniques are described. The importance of standardisation of methods is emphasised and recently published methods are reviewed. (31 refs.) *M.O.*

72857 Luminescence as an indicator of spatial distribution of Mn^{2+} ions in TGS crystals. J.Mroz, S.Gebela (Inst. of Phys., Tech. Univ. of Wroclaw, Wroclaw, Poland).
Opt. Appl. (Poland), vol.12, no.3-4, p.403-9 (1982).
Presents evidence of the spatial distribution of luminescence in TGS crystals doped with manganese. The observations were carried out in the XZ-plane. A strongly polarized blue luminescence in the growth pyramid (001) as well as a green luminescence in the (203) pyramid without any oriented centres were detected. Spectral distributions and luminescence excitation spectra are shown. In these spectra some differentiation in the charge transition spectral region

and an appearance of bands connected with d-d transitions are stated. (11 refs.)

72858 Radiative unstabilities in some triple electronic colour centre systems in ionic crystals. A.A.Berezin (Dept. of Engng. Phys., McMaster Univ., Hamilton, Ontario, Canada).
Phys. Lett. A (Netherlands), vol.95A, no.5, p.266-8 (2 May 1983).
The principal unstability of some polyvalent triple impurity systems against the possibility of radiative tunnel transitions (RTTs) is discussed. As an example, a three-centre system of neutral, negatively charged and positively charged F-, F′-and α-colour centres in an alkali halide crystal is considered. It the distance between F- and F′-centres is much smaller than the F′-α distance then, along with a very slow RTT process, $F'+\alpha \rightarrow 2F$, a much faster RTT process $F'(b)+F(1) \rightarrow F(h)+F'(1)$ is also possible. Here, h and 1 denote the relatively higher and lower energy position of the trapping level for an extra electron at two F-sites caused by their different distances from the charged α-centre. This type of radiative unstabilities could be relatively significant in areas of defect clustering. (10 refs.)

72859 Subnanosecond total-light decay and spectra in α-Si:H. B.A.Wilson, P.Hu, J.P.Harbison, T.M.Jedju (Bell Labs., Murray Hill, NJ, USA).
Phys. Rev. Lett. (USA), vol.50, no.19, p.1490-3 (9 May 1983).
With use of an ultrafast Ge photodiode and a high-power picosecond laser system, the fastest radiative processes in plasma-deposited *a*-Si:H have been resolved. Spectrally integrated measurements on a 250-ps time scale provide a simple picture that for the first time isolates single rates in the recombination dynamics, permitting quantitative physical modeling. Spectral shifts are observed on time scales faster than the radiative decay, providing clear evidence of slow relaxation processes. (14 refs.)

72860 Electronic properties of heavily-doped n-type silicon. A.Selloni, S.T.Pantelides (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.78-80 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Heavy doping has been known to reduce the energy gap of semiconductors, affecting the characteristics of many devices. In the case of Si, theoretical work has so far focused on calculating the reduced gaps. Despite the extensive calculations, however, no meaningful comparison of theory with experiment has been achieved because there exist major discrepancies in the values of the gap extracted from different experiments. In this paper, the authors point out that these discrepancies arose because the data were fitted by assuming simple models for different properties and report calculations of the photoluminescence spectra of n-type Si for various impurity concentrations. They find that intervalley scattering, previously considered negligible, is essential in order to reproduce the major experimental features and trends. (14 refs.)

72861 Disorder and N-N transfer mechanism in nitrogen-bound exciton luminescence of GaP_xAs_{1-x}:N systems. H.Mariette, V.Thierry-Meig, J.Chevallier (Lab. de Phys. des Solides, CNRS, Meudon, France), P.Leroux Hugon.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.102-4 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Temperature and nitrogen concentration dependences of the luminescence and excitonic spectra in GaP_xAs_{1-x}:N systems give evidence for a hopping transfer mechanism of excitons between states of a disorder-broadened band. CPA calculations are also reported. (12 refs.)

72862 Momentum-space condensation of probe-injected biexcitons into a strongly pumped biexciton state in CuCl. N.Peyghambarian, L.L.Chase (Indiana Univ., Bloomington, IN, USA), A.Mysyrowicz.
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.299-300 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Two sets of new results are presented which confirm the occurrence of a Bose-Einstein condensation of biexcitons in CuCl. First, luminescence spectra recorded under well controlled conditions yield the distribution function of the particles, which takes the form of a strongly degenerate Bose-Einstein distribution under increasing excitation, with μ up to 0. Second, probe particles injected into the system in the presence of the presumed condensate are observed to coalesce into it. (4 refs.)

72863 The role of iodine for the luminescence of highly excited AgBr. Th.Kleinefeld, H.Stolz, W.von der Osten (Fachbereich Naturwissenschaften I, Experimentalphys., Univ.-Gesamthochschule, Paderborn, Germany).
Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.306-8 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).
Using time-resolving techniques, the recombination luminescence observed under high power excitation at low temperature is studied in nominally pure AgBr that systematically varies in iodine impurity content. Several new features in the luminescence spectrum are observed that are correlated with iodine concentration. On the basis of these results, including energy positions and lineshapes, the high excitation luminescence is consistently explained in terms of recombination of a biexciton bound to iodine. Intervalley exciton scattering by X-phonons known to be an important relaxation mechanism in AgBr has to be considered to fully account for the observed lineshapes. (9 refs.)

72864 Photoluminescence efficiencies and yields in disordered systems. T.M.Searle (Dept. of Phys., Univ. of Sheffield, Sheffield, England).
Solid State Commun. (USA), vol.46, no.4, p.291-3 (April 1983).
The photoluminescnece efficiency and yield of a simple system consisting of a single radiative centre surrounded by a random distribution of non-radiative centres are considered. It is shown that the ensemble averages for both these quantities are identical and given by a double integral. Upper and lower limits on this average are derived, and it is shown that the lower limit also provides a rapidly evaluated approximation to the exact average for most realistic transfer functions, which is accurate to within about 10%, over at least five orders of magnitude fall of efficiency. (7 refs.)

72865 Isotope shifts for the P, Q, R lines in indium-doped silicon. T.E.Schlesinger, R.J.Hauenstein, R.M.Feenstra, T.C.McGill (California Inst. of Technol., Pasadena, CA, USA).
Solid State Commun. (USA), vol.46, no.4, p.321-4 (April 1983).
The authors have measured the isotope shift of the P and R luminescence lines in Si doped with In and diffused with isotopically enriched Fe. They find no measurable shift in the R line. Similar experiments on the luminescence line attributed to an isolated Fe complex show no shift in the previously identified 'phonon replicas'. Theoretical calculations of defect phonon resonances near 9 meV for interstitial and substitutional Fe predict an isotope shift of 0.17 meV for ^{56}Fe and ^{54}Fe. This value is in disagreement with the observed lack of a shift. (12 refs.)

72866 Observation of the internal luminescence of $Cr^{2+}(3d^4)$ in GaAs under hydrostatic pressure. B.Deveaud, G.Picoli (CNET (LAB/ICM),,France). Lannion, Y.Zhou, G.Martinez.
Solid State Commun. (USA), vol.46, no.4, p.359-62 (April 1983).
Observation of the internal luminescence of $Cr^{2+}(3d^4)$ in GaAs under hydrostatic pressure is reported. The activation of this luminescence is correlated to the lifting of the degeneracy between the excited level of Cr^{2+} and the conduction band of the host material. The possible mechanisms giving rise to this luminescence are discussed. (15 refs.)

72867 Effect of electron-phonon interaction on the photoluminescence of single crystals of BiI_3. M.P.Lisitsa, F.V.Motsnyi (Inst. of Semiconductors, Acad. of Sci., Kiev, Ukrainian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1765-6 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3120-2 (Oct. 1982). [received: April 1983]
The photoluminescence spectra of single crystals of BiI_3 at T=4.2K contain an extremely wide asymmetric band λ=0.9 μ, whose half-width is 173 meV. This band is due to associated defects, which may contain impurity atoms of Ag, Pb, Ag+Pb, Cu, As and Sb. The authors clarify the nature of this band by comparing data on its half-width and its contour with the results of the Pekar-Krivoglaz theory (1953, 1956), which takes electron-phonon interaction into account. (9 refs.)

72868 Dependence of the properties of a nonequilibrium degenerate electron-hole plasma on the energy of the exciting photons in ZnTe crystals. M.S.Brodin, V.M.Bandura, I.I.Zheru, M.G.Matsko (Inst. of Phys., Acad. of Sci., Kiev, Ukrainian SSR).
Sov. Phys.-Solid State (USA), vol.24, no.10, p.1774-5 (Oct. 1982). Translation of: *Fiz. Tverd. Tela (USSR)*, vol.24, no.10, p.3133-6 (Oct. 1982). [received: April 1983]
The authors show for the first time that the luminescence bands of a nonequilibrium degenerate electron-hole plasma can be simply and unambiguously identified with the aid of a tunable laser. They have studied the features of the luminescence spectra of ZnTe single crystals under intense excitation by a tunable coumarin-30 dye laser having a pulsed power of 20 kW and a pulse length of 8 nsec. The measurements were made on a diffraction spectrograph having a dispersion 7.2 Å/mm with a stroboscopic recording technique. (6 refs.)

78.60 OTHER LUMINESCENCE SPECTRA AND RADIATIVE RECOMBINATION

(for photoconduction and photovoltaic effects, see 72.40; for photoluminescence, see 78.55)

72869 Increase of the efficiency of emission of light by surface plasma oscillations in metal-barrier-metal-liquid crystal structures. E.M.Belenov, I.N.Kompanets, A.V.Parfenov, Yu.M.Popov, I.A.Poluektov, S.I.Sagitov, E.M.Soboleva, A.G.Sobolev, A.V.Uskov, V.G.Tsukanov (P.N. Lebedev Phys. Inst., Acad. of Sci., Moscow, USSR).
Sov. J. Quantum Electron. (USA), vol.12, no.11, p.1496-7 (Nov. 1982). Translation of: *Kvantovaya Elektron., Moskva (USSR)*, vol.9, no.11, p.2306-7 (Nov. 1982). [received: May 1983]
An increase in the efficiency of light emission (by over an order of magnitude) was achieved for plasma oscillations in a thin silver film of a gold-aluminum oxide-silver (Au-Al_2O_3-Ag) structure by altering the permittivity of a nematic liquid crystal adjoining the silver film. (4 refs.)

78.60F Electroluminescence

72870 Electroluminescence in RF sputtered ZnS:TbF_3, Mn thin films. A.Mikami, K.Ando (Dept. of Electrical Engng., Osaka City Univ., Osaka, Japan).
Mem. Fac. Eng. Osaka City Univ. (Japan), vol.23, p.39-46 (Dec. 1982). [received: May 1983]
For the purpose of preparing electroluminescent (EL) devices with various color, ZnS:TbF_3, Mn thin films were formed by RF sputtering using a target which was a mixture of ZnS, TbF_3 and MnS powders. Dependence of electroluminescence spectrum of the EL device on the concentrations of TbF_3 and MnS in the target were investigated in detail. The spectrum usually consists of four emission bands in the visible-light region. First two bands around 490 and 545 nm are due to the Tb-F complex center, the third around 585 nm is due to the Mn single center, and the fourth around 710 nm is due to the Mn-F complex center. The intensity ratio between emissions originating in the Tb-F and the Mn centers can be easily controlled by adjusting the concentrations of $TbF_3$and MnS in the target, and the color of light emitted by the device varies from green to orange with increasing composition ratio of MnS

to TbF_3. The red emission around 710 nm with very weak intensity relative to others hardly affected the emission color of the EL device. (11 refs.)

72871 Hot-electron picture of light emission from tunnel junctions. J.R.Kirtley, T.N.Theis, J.C.Tsang, D.J.DiMaria (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
Phys. Rev. B (USA), vol.27, no.8, p.4601-11 (15 April 1983).
Metal-insulator-metal tunnel junctions emit optical radiation when biased at voltages in the range 2-4 V. The authors argue that a complete picture of this radiation process includes hot electrons which excite surface electromagnetic resonances, which are in turn coupled to external radiation though surface roughness. This picture is supported by measurements of the temperature and second-metal-electrode thickness dependence of the emission intensities, and by light emission from surface plasmons excited by optical pumping and by charge injection. (28 refs.)

72872 Electroluminescence of GaAs single crystals at 300K. A.G.Bagirov, S.Yu.Bagirov, E.Yu.Salaev (Inst. of Phys., Acad. of Sci., Baku, Azerbaidzhan SSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1397 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2166-7 (Dec. 1982). [received: May 1983]
The authors present the results of the first study of electroluminescence of GaS single crystals at 300K. Electroluminescence was excited by an alternating (sinusoidal) voltage. Experiments showed that GaS single crystals with InGa contacts emitted stronger electroluminescence than those with In contacts. A visual examination showed that electroluminescence was concentrated around the metal electrode and it appeared in the form of separate spots emitting different colors. (7 refs.)

78.60H Cathodoluminescence, ionoluminescence

72873 Spatial distribution of photons with a continuous spectrum emitted by sputtering products. S.F.Belykh, V.I.Veksler (Tashkent Lenin State Univ., Tashkent, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.163-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1389-94 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
An important parameter characterising the continuous optical spectrum emitted by sputtering products is the spatial intensity distribution, I(x), in the halo of the emission. The authors determine I(x) for a variety of transition and rare earth metals. Within the framework of the two-photon mechanism, they show that the difference in the shape of the I(x) curves for the two series of metals may be due to the fact that the two-photon transition probability should be higher for lanthanides. (18 refs.)

72874 Cathodoluminescence of anodically grown SiO_2 films. P.A.Pundur, E.A.Slotsenietse, Yu.A.Tarantov, Y.V.Bulavinov.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.50-3 (1983). In Russian.
The properties of thermally and anodically grown SiO_2 films have been studied by methods of cathodoluminescence and C-V characteristics. It is established that there are identical types of intrinsic defects in both the SiO_2 films though the concentration and distributions of the defects are not equal. The electrolyte has been used as a source of impurity defects in thin SiO_2 films. It is concluded that the anodic polarization in the electrolyte with a high electrical field changes the structure of thermally grown SiO_2 films approaching the structure of the anodic SiO_2 films. (8 refs.)

72875 A simple, high collection efficiency cathodoluminescence imaging technique: application to GaSb and CdTe. A.K.Chin (Bell Labs., Murray Hill, NJ, USA).
Scanning Electron Microsc. (USA), pt.3, p.1069-75 (1982).
Spatially resolved cathodoluminescence (CL) imaging is a powerful method for evaluating the quality of luminescent materials. However, sophisticated collection optics, which are not commercially available, are generally required for CL evaluation of materials with low luminescence efficiency. In this paper, a simple, high collection efficiency CL technique is used to reveal defects in CdTe and growth striations in GaSb. A solid state photodiode is used within the sample chamber of the scanning electron microscope to detect the CL emission. Features observed in the CL images of both semiconductors are correlated with those revealed by a defect etchant. For GaSb, the carrier concentration is found to be directly proportional to the CL intensity. For the samples used in this study, the variations in CL intensity and thus the carrier concentration within the growth striations are estimated to be ~20%. (9 refs.)

Extremely rapid outdiffusion on *n*-type impurities in InP ......See Entry 72163

78.60K Thermoluminescence

72876 Thermoluminescence of Al_2O_3 layers formed by anodic oxidation in oxalic acid. R.Dragon, S.Marzec (Phys. Lab., Higher School of Engng., Opole, Poland).
Opt. Appl. (Poland), vol.12, no.3-4, p.433-43 (1982).
Thermoluminescence (TL) of Al_2O_3 layers obtained by electrolytic oxidation of aluminium in aqueous solution of oxalic acid has been investigated. It has been found that the Al_2O_3 layers show both the natural (without excitation) as well as the UV-excited thermoluminescence. By applying the method proposed by Alencev-Fok (1972) and Antonov-Romanovskii (1966) it has been shown that in the case of the layers formed at DC voltage the TL-curve consists of 5 and 3 elementary glow-peaks depending on whether thermoluminescence is natural or stimulated. For the layers formed at AC voltage 2 or 6 elementary glow-peaks were observed, respectively. For all the observed elementary glow-peaks the activation energy of the electron traps has been calculated. (16 refs.)

72877 Regenerated thermoluminescence. S.Charalambous, F.Hasan (Nuclear Phys. Dept., Univ. of Thessaloniki, Thessaloniki, Greece).
Phys. Lett. A (Netherlands), vol.95A, no.5, p.259-62 (2 May 1983).
A regenerated, non-radiation induced TL was observed. Results versus dose, storage time, storage temperature, maximum first heating, are presented. For the phenomenon a theoretical model is given, based on the formation of a peculiar composite defect from migrated defects and trapped electrons. (4 refs.)

Hole-induced exoelectronic emission ......See Entry 72972

78.65 OPTICAL PROPERTIES OF THIN FILMS

72878 Elementary surface excitations in insulators and metals. Methods of spectral examination. G.N.Zhizhin, E.A.Vinogradov, M.A.Moskaleva, V.A.Yakovlev (Spectroscopy Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.76-81 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1097-103 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
A survey is presented of methods of examining surface and thin films using surface-excitation spectroscopy. Surface-polariton spectroscopy for insulators enables one to examine thin films of metals and insulators on crystals. The thermally stimulated emission of surface polaritons has been used to examine thin crystalline films and single crystals. Surface-electromagnetic wave spectroscopy is a very sensitive method of examining the surface state of a metal mirror and also for detecting roughness, oxide layers, and contaminants. (28 refs.)

72879 The role of rate of deposition and substrate temperature on the structure and loss of zinc sulphide and magnesium fluoride films. A.A.J.Al-Douri, O.S.Heavens (Phys. Dept., Univ. of York, Heslington, England).
J. Phys. D (GB), vol.16, no.5, p.927-35 (14 May 1983).
By the use of an integrating sphere, the scattering losses in films of magnesium fluoride and zinc sulphide have been measured as functions of deposition rate and of substrate temperature. It is established that an optimum deposition rate exists and that scattering losses increase with increasing substrate temperature. Electron micrographs of the films reveal structural features which generally correlate with scattering observations. Over a wide range of deposition rates, the scattering results agree with those using other methods. There is a suggestion that for zinc sulphide part of the losses at very high deposition rates arise through absorption rather than through scattering. (6 refs.)

72880 Angular scan spectrum of a surface plasma excitation on a Schottky diode. J.Derov, Y.Y.Teng, A.S.Karakashian (Dept. of Phys. & Appl. Phys., Univ. of Lowell, Lowell, MA, USA).
Phys. Lett. A (Netherlands), vol.95A, no.3-4, p.197-200 (25 April 1983).
The reflectivity and quantum efficiency response functions of a Schottky-barrier diode are measured in an angular scan attenuated total reflection experiment. The excitation of the surface plasma resonance is observed in both of these response functions. Improvements in the quantum efficiency of the diodes over the normal incidence case by factors of from 1.5 to 11.5 are obtained when the surface plasma resonance is excited. (5 refs.)

72881 Optical properties of epitaxial $PbS_{1-x}Se_x$ films. A.A.Sinyatynskii, A.P.Shotov (P.N. Levedev Phys. Inst., Acad. of Sci., Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1413-14 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2187-90 (Dec. 1982). [received: May 1983]
The authors study the electrical and optical properties of $PbS_{1-x}Se_x$ epitaxial films near the fundamental absorption edge. They report measurements on the optical transmission, refractive index, carrier density and carrier mobility. (8 refs.)

72882 Changes in the absorption at energies smaller than the optical band gap of hydrogenated amorphous silicon in the Staebler-Wronski effect. V.S.Vavilov, A.G.Kazanskii, E.P.Milichevich (M.V. Lomonosov State Univ., Moscow, USSR).
Sov. Phys.-Semicond. (USA), vol.16, no.12, p.1417-18 (Dec. 1982). Translation of: *Fiz. & Tekh. Poluprovodn. (USSR)*, vol.16, no.12, p.2192-4 (Dec. 1982). [received: May 1983]
The effects exhibited by hydrogenated amorphous silicon (α-Si:H) include the reversible changes in the dark conductivity σ_d and in the photoconductivity σ_{ph}, observed after illumination of a sample with light of photon energy $h\nu=1.6$-2.0 eV: this is known as the Staebler-Wronski effect. The authors investigate the influence of prolonged illumination of α-Si:H on the form of the $\alpha(h\nu)$ absorption spectra at energies lower than the band gap ($h\nu<1.8$ eV). (13 refs.)

78.70 OTHER INTERACTIONS OF MATTER WITH PARTICLES AND RADIATION

78.70B Positron annihilation

(see also 71.65 Positron states)

72883 **Measurement of 3γ annihilation of positron using Ge(Li) detector.** Wu Gun-hung, Wang Yun-yu, Tang Hsiao-wei (Inst. of High Energy Phys., Acad. Sinica, Beijing, China).
Acta Phys. Sin. (China), vol.32, no.3, p.417-22 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
A method for measuring the positron 3γ annihilation with Ge(Li) detector is introduced, in which the relative yields of 3γ annihilation is measured by the counts of the 511 keV peak only. The authors call it the 'peak method', and compare it with the 'peak-valley method'. (7 refs.)

72884 **Determination of the ferromagnetic vacancy-formation enthalpy in α-iron by the positron method using the carbon-vacancy pair as a probe.** L.de Schepper (Materials Phys. Group, Limburgs Univ. Centrum, Diepenbeek, Belgium), D.Segers, G.Knuyt, L.Dorikens-Vanpraet, M.Dorikens, L.Stals, P.Moser.
Phys. Lett. A (Netherlands), vol.95A, no.2, p.121-3 (18 April 1983).
The 511 keV positron annnihilation lineshape was measured as a function of temperature between 600 and 1183K in extremely pure and carbon-doped (50 and 750 appm C) iron. Whereas in pure iron no trapping of positrons is observed below the Curie temperature (1043K), trapping in carbon-vacancy pairs is observed in this temperature range in the carbon-doped samples. This allowed the authors to determine the ferromagnetic vacancy-formation enthalpy as 2.0±0.2 eV. (16 refs.)

78.70D X-ray absorption and absorption edges

72885 **Large anisotropic vibrational correlations in *A*15 Nb_3Ge.** G.S.Cargill,III, R.F.Boehme, W.Weber (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
Phys. Rev. Lett. (USA), vol.50, no.18, p.1391-4 (2 May 1983).
Extended X-ray-absorption fine-structure measurements on Nb_3Ge at temperatures from 8 to 300K using the Nb *K* edge show large anisotropies in nearest-neighbor vibrational correlations arising from one-dimensional transition-metal chains in the A15 structure. A simple view of these vibrations involves combinations of optical phonons which cause chains of Nb atoms to vibrate, nearly undistorted within the BCC lattice of Ge atoms, uncorrelated with vibrations of adjacent, perpendicular Nb chains. (10 refs.)

72886 ***f*-count effects in X-ray-absorption spectra of the 3*d* levels in Ce and its intermetallic compounds.** J.C.Fuggle, F.U.Hillebrecht (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany), J.-M.Esteva, R.C.Karnatak, O.Gunnarsson, K.Schonhammer.
Phys. Rev. B (USA), vol.27, no.8, p.4637-43 (15 April 1983).
The 3*d* X-ray-absorption spectra of Ce, $CeSn_3$, CeAu, CePd, Ce_3Pd_5, $CePd_3$, $CeNi_2$ and $CeNi_5$ have been studied. Results of theoretical calculations of the 3*d* absorption spectra are also reported. Comparison with theory shows that the observed spectra are compatible with photoemission-derived 4*f*-level widths, arising from hybridization with the conduction states, of 30-130 meV and *f* counts greater than 0.8, in all the compounds studies. The relative merits of X-ray-absorption spectroscopy as a tool for the study of Ce compounds are briefly discussed. (45 refs.)

72887 **Structural and electronic properties of Fe and TiFe from extended and near-edge X-ray-absorption structure.** N.Motta (Scuola Normale Superiore, Pisa, Italy), M.De Crescenzi, A.Balzarotti.
Phys. Rev. B (USA), vol.27, no.8, p.4712-21 (15 April 1983).
The extended X-ray-absorption fine structure of Fe and TiFe has been measured above the edges of Fe and Ti at 80 and 300K. In both materials the fifth and sixth coordination shells show clear evidence of multiple-scattering effects due to the intervening first- and second-shell atoms. The plane-wave approximation for the scattering is found to be inadequate and corrections for the wave curvature are made to the backscattering phase shifts of the first shell. The first peak of the radial distribution function of Fe and TiFe is decomposed into its constituents by means of the beat method. The local order of TiFe around both Ti and Fe atoms is good up to the sixth coordination shell. It is shown that the near-edge structure of both Ti and Fe *K* edges of TiFe reflects the local state density of *p*-like symmetry at the titanium site, in agreement with detailed partial-density-of-states calculations. (25 refs.)

72888 **X-ray spectra and electronic structure of titanium, zirconium and hafnium gallides.** Ya.I.Dutchak, I.D.Shcherba, B.N.Yatsyk.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.559-63 (April 1983). In Russian.
An X-ray spectral analysis is carried out for the electronic structure of titanium, zirconium and hafnium gallides. The same order of sequence is established for the electronic states of different symmetry which form the valence zone of transition metal gallides. A joint consideration of the calculated interatomic distances of crystal structures of the halides with results of X-ray spectral analysis allowed a conclusion on the nature of interatomic interaction in the investigated compounds to be made. 72889 **Binding energy of electrons of surface atoms of oxidized 3d transition metals, obtained by the method of appearance-potential spectroscopy.** M.A.Vasil'ev, V.T.Cherepin, O.A.Yakubtsov (Inst. of Metal Phys., Acad. of Sci., Ukrainian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.119-22 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1342-5 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors examined high-temperature oxidation of 3d transition metals in an atmosphere of pure oxygen using the method of spectroscopy of appearance potentials of soft X-ray emission (SAPSX) and Auger electron spectroscopy (AES), which yield information on the binding energy of electrons and on the composition of the surface layer around 1 nm thick. (16 refs.)

72890 **The surface chemical bonding investigation of CVD coated tool-steel.** A.Szasz, L.Kertesz, J.Kojnok (Inst. for Solid State Phys., Eotvos Univ., Budapest, Hungary), M.Kovats, S.Z.Csih.
Vacuum (GB), vol.33, no.1-2, p.43-7 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Investigates the special cutting tool-steel, coated with TiC and TiN compounds. The tools were tested in different states by soft X-ray emission spectroscopy (SXES) in the regions of the CK_α, NK_α, FeL_α and OK_α emission peaks of the compounds, and they were investigated at different depths of the coating layer. The emission lines of the steel holder and its surroundings appear at depths of more than 600 nm. Shifts of the OK_α peak and the fine structure changes in it show clearly the corrosion steps and states of the used tools, corresponding to the degree of use. The measurements prove clearly that heat treatment is a sensitive step in the technology of preparation of the CVD coated tool-steel. Exposure to oxygen during heat treatment decreases the life of the tool drastically. (11 refs.)

72891 **The changes of the electron states depending on the depth of surface layers of Al-based alloys.** L.Tolnai (Coll. of Transport & Telecommunication, Gyor, Hungary), L.Kertesz, A.Szasz, J.Kojnok.
Vacuum (GB), vol.33, no.1-2, p.59-61 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
The method of soft X-ray emission spectroscopy (SXES) offers the possibility to study the chemical bonding of the oxidization layer, and the complex oxide. In the authors' investigation the corrosion states of the pure aluminium and the oxide wear-resistant layer of an Al-based alloy was studied. The surface layer from 10 nm to 550 nm was investigated. The corrosion states of the pure Al showed the changes of bondings and a change in concentration depending on the penetration depth of the corrosion processes. The studies of the wear-resistant oxide layers contain the measurements of the components of the alloy too. The authors present the systematic changes of the chemical components. The researches show the complex oxide and carbide compounds characterizing the layers which have good tribological parameters. Their results point out the important features for the technology to create wear-resistant layers. (7 refs.)

72892 **Changes in AlMgSi surface layers at different temperatures.** L.Kertesz, A.Szasz, J.Kojnok (Inst. for Solid State Phys., Eotvos Univ., Budapest, Hungary), A.A.Katsnelson.
Vacuum (GB), vol.33, no.1-2, p.63-6 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
It is possible to determine temperature ranges caused by electron beams under high voltage conditions. Combining the radiation power of SXES equipment with DTA curves the authors were able to make conclusions concerning the temperature range during radiation time. Heat treatments under vacuum and continuous SXES measurements show a shift of the Fermi level and a change in the fine structure of the AlMgSi surface. (15 refs.)

72893 **The SXES study of the amorphous Ni-P compounds.** A.Szasz, L.Kertesz, J.Kojnok (Inst. for Solid State Phys., Eotvos Univ., Budapest, Hungary), Z.Hegedus, L.Tolnai.
Vacuum (GB), vol.33, no.1-2, p.107-10 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
The aim of this work is the study of the electron states of Ni-P compound layers made by an electroless technique using soft X-ray emission spectroscopy (SXES). The information from SXES depends on the thickness and state (amorphous or crystalline) of the samples. There is a systematic change in the emission lines of nickel and phosphorus between the amorphous and crystalline states. In the amorphous state the main peaks are shifted and the fine structure has a blurred shape as compared to the crystalline state. The shift and the fine structure changes in spectra can be explained by the transformation of the chemical bonds and the symmetries within the compounds. The difference in fine structure of the Cu emission line caused by the chemical bonds due to the surface covering is also studied. (13 refs.)

72894 Laser-induced surface reconstruction of semiconductors and metals. J.M.Moison, M.Bensoussan (Dept. OMT/PMS, CNET, Bagneux, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.294-300 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The authors have investigated the influence of pulsed laser irradiation on the surface structure of Si(111), GaAs(100), InP(100), and Au(100). The surface of these materials shows an equilibrium LEED pattern that can be described by a $(m \times n)$ reconstruction, and no (1×1) pattern is observed at room temperature, except by impurity stabilization. The preparation of a clean (1×1) surface is of interest, because it would lead to a considerably easier theoretical evaluation. Pulsed laser irradiation is now believed to be a means to prepare such surfaces. However, the authors show that the surfaces obtained are not defect-free. They have irradiated clean reconstructed surfaces with increasing laser fluences. Above a threshold fluence, the superstructure LEED spots disappear, leaving only the (1×1) pattern and a slight increased background. A more detailed examination of the LEED patterns reveals a random distribution of steps beside ordered terraces. The step height is nearly equal to the bulk interplanar distance. The interstep spacing ranges from 70 Å for Si to 30 Å for InP and GaAs and 15 Å for Au. It is shown that these steps stabilize the (1×1) pattern. (17 refs.)

72895 AES and EELS study of hydrogen adsorption, oxygen adsorption and sulphur segregation on a clean titanium surface. F.Pellerin, J.P.Langeron (Centre d'Etudes de Chimie Metallurgique du CNRS, Vitry-sur-Seine, France).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.444-7 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The Auger electron spectra (AES) and electron energy loss spectra (EELS) of a clean and hydrogen, oxygen, sulphur covered titanium sample were recorded with a cylindrical mirror analyzer. Information on the valence electron density of states is derived from the shape of the $M_{23}VV$ Auger transition of titanium and of the EELS spectrum. It is shown that, while hydrogen or oxygen adsorption induce a resonance 5 eV below the Fermi level, sulphur segregation does not perturb strongly the valence electron levels of titanium. (4 refs.)

72896 Quantitative AES of binary alloys: a comparison between handbook and pseudo-first principles corrections. S.Mroczkowski (Midwest Res. Microscopy Inc., Milwaukee, WI, USA), D.Lichtman.
Surf. Sci. (Netherlands), vol.127, no.1, p.119-34 (April 1983).
Quantitative Auger electron spectroscopy of a number of binary alloys was studied. A pseudo-first principles correction scheme was applied to series of chromium/iron, chromium/nickel, and copper/gold alloys. Peak-to-peak height ratios of differentiated spectra were corrected for elemental differences in ionization cross section, Auger transition probability, atomic density, electron escape depth, backscattering factor, and sputter yield. These corrections changed the original ratio by factors ranging from 1.12 (for the chromium/iron series with a 10 kV primary electron beam) to 4.63 (for the copper/gold series with a 5 kV primary beam). The calculated surface concentrations were compared to wet chemistry bulk concentrations and in all cases, this first principles correction was an improvement over using uncorrected peak height ratios for concentration determination. For a 50/50 at% alloy in each series, the corrected data error for the chromium/iron alloy was 15%, for the chromium/nickel alloy was 2%, and for the copper/gold alloy was 36%. In all series except the chromium/iron system, concentrations obtained using this method had a smaller error than concentrations obtained using sensitivity factors from the Handbook of Auger Electron Spectroscopy. (22 refs.)

72897 Electron beam-solid interactions: implications for high spatial resolution Auger electron spectroscopy. L.L.Levenson (Dept. of Phys. & Energy Sci., Univ. of Colorado, Colorado Springs, CO, USA).
Scanning Electron Microsc. (USA), pt.3, p.925-36 (1982).
Primary electron beams with energies ranging from 10^3 to 10^4 eV and currents between 10^{-3} and 10^{-5} A are commonly used for Auger electron spectroscopy (AES). Electron-electron scattering causes the beam to spread and lose energy as it penetrates the material. The scattering processes are manifested in the energy spectrum of electrons emitted from the surface. This spectrum presents a record of elastic scattering, single and multiple collision inelastic scattering, Auger electron emission, plasmon generation and decay, and secondary electron emission. Electron-electron interactions can cause chemical and structural changes in the sample. Therefore, the spectrum of emitted electrons may change with time. In general, AES requires low effective beam current densities in order to avoid significant electron beam damage. Therefore, low electron beam currents (low nA range) must be used in high spatial resolution AES. Point analysis with a stationary beam may require pA currents to avoid damage when the beam diameter is the order of 10-100 μm. Under all circumstances, ultra high vacuum conditions are needed to avoid electron beam stimulated adsorption or desorption of adsorbed gases. A brief introduction to these subjects is presented. Some guidelines are given for avoiding electron beam damage during high spatial resolution Auger electron spectroscopy. (51 refs.)

72898 The elastic peak in AES and EELS. G.Gergely (Res. Inst. for Tech. Phys., Hungarian Acad. of Sci., Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.89-91 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Elastic peak electron spectroscopy (EPES) determines the spectra of secondary electrons in absolute units in the vicinity of the elastic peak including also loss peaks. The percentage of elastically reflected electrons N_e is determined by comparing the peak to total spectrum area. Quantitative data can be deduced from the measurement of the coefficient of secondary emission or electron reflection. N_e is mainly determined by the atomic number for medium energy excitation (1-3.2 keV). It can be used as reference for quantitative AES or EELS. This paper deals with the application of EPES. Results obtained on the backscattering cross section of C, Si, Ge, Mo, W, and Au are presented. The K core level ionization cross section of carbon was determined. The volume plasmon loss process is discussed. EPES was used for evaluating some experimental results on the excitation cross section of a silicon surface state and vibrations of CO adsorbed on Pt have also been determined. (17 refs.)

79.20H Electron impact: secondary emission

72899 Effect of crystalline structure of a rigid body on elastic reflection of intermediate-energy electrons. V.V.Rumyantsev, V.V.Korablev, V.V.Dubov, Yu.A.Morozov (Leningrad Kalinin Polytech. Inst., Leningrad, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.113-18 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1336-41 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The cross sections of elastic and inelastic electron scattering by large angles in single crystals, like the secondary electron emission coefficients, have a component that oscillates as the angle of incidence θ of primary electrons on the crystal (or their energy E_p) varies. These oscillations are due primarily to diffraction of electrons that penetrate the crystal, which causes, for different angles θ and energies E_p, a change in the conditions of noncoherent scattering of diffracted electrons. Of the entire spectrum of secondary electrons, elastically reflected electrons and electrons that have lost an energy on the order of the plasmon energy are the most sensitive to diffraction processes. Therefore the fine structure is much more evident on the dependences of the elastic scattering coefficient R of electrons on the energy E_p and angle θ, than on the analogous dependences for the coefficients of secondary electron emission σ and inelastic reflection η. The authors generalize the experimental data on the form of the function $R(E_p)$, construct a theory of the phenomenon, and offer a comparison between theory and experiment. The objects of study were single-crystal specimens of (111) Si, (111) Mo, (110) Mo, (112) W, (111) Nb. (4 refs.)

72900 Some features of true secondary electron emission of island-type gold films. S.A.Nepiiko, V.I.Stepkin.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.144-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1367-71 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The studies show that the accuracy in measuring the potential distribution in island-type films by the method of secondary-emission electron spectroscopy is limited primarily by the dependence of the true secondary emission current on the thickness by weight, i.e. on the size and density of the islands per unit surface of the substrate, whereas the shape of the energy distribution of secondary electrons is virtually independent of the thickness. Measurement accuracy can be enhanced by selecting a primary electron energy such that the dependence of the secondary-emission current on the thickness is at a minimum, and by normalizing the energy distribution of secondary electrons with respect to amplitude. (12 refs.)

72901 Application of reciprocity theorem to secondary electron emission of single crystals. M.V.Gomoyunova, I.I.Pronin, D.P.Bernatskii, S.L.Zaslavskii (Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.149-52 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1372-6 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors offer an experimental study of diffraction of primary and secondary electrons of moderate energies by {100} Mo single crystals, and an explanation (involving the use of orientation effects) of secondary electron emission for the range of electron energy losses where the reciprocity theorem is satisfied. Data on anisotropy of excitation and exit of SE are also important in conjunction with the development of quantitative method of electron spectroscopy of surfaces of solids, as well as of scanning reflection electron microscopy. (5 refs.)

72902 Energy structure of surface region of tungsten single crystal as expressed in the secondary-electron spectrum. O.M.Artamonov, O.M.Smirnov, A.N.Terekhov (Leningrad State Univ., Leningrad, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.158-62 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1383-8 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors consider the formation of the energy spectrum of secondary electrons upon emission from the surface layer of crystal, where the energy structure of the layer may differ from the bulk energy structure. Its thickness depends on the preferential electron-scattering mechanism and is defined by the corresponding phenomenological parameters. In the approximation of a constant transition matrix element, for the limiting cases of predominantly elastic or inelastic electron-electron scattering they obtain expressions that relate the energy distribution of SE and the energy structure of the emitting layer of the single crystal. They employ the one-electron approximation. It is shown that a structure appears in the SE spectrum when the energy structure

of the emitting layer of the single crystal cannot be described in the approximation of an almost free electron gas and, as experiments show, it approaches the bulk energy band structure. It is also shown that when the energy structure of the emitting layer is satisfactorily described by the model of an almost free electron gas, the SE spectrum is characterized by the traditional cascade maximum. (11 refs.)

72903 Quantum size effect in electron transmission through Cu and Ag films on W(110). B.T.Jonker, N.C.Bartelt, R.L.Park (Dept. of Phys. & Astron., Univ. of Maryland, College Park, MD, USA).
Surf. Sci. (Netherlands), vol.127, no.2, p.183-99 (April 1983).
The transmission coefficient of very low electrons (≤ 10 eV) normally incident on (111) epitaxial films of Cu and Ag on W(110) is modulated by interference between scattering from the vacuum/metal and metal/metal interfaces. Comparison with calculations of free-electron scattering from a one-dimensional potential model, in which grading of the metal/metal interface is represented by a smoothing of the potential step, indicates that this interface is abrupt within approximately one layer spacing. The authors obtain a value of 11.0 (8.0)$\pm$1.0 eV for the inner potential of Cu (Ag) and mean free path lengths of 39$\pm$8 Å at an energy of 7.0 eV relative to the Fermi energy and 29$\pm$11 Å at 9.0 eV for Cu, and 25$\pm$10 Å at 7.5 eV for Ag. Work function values are obtained by the field emission retarding potential technique. They investigate the effects of the surface potential barrier, inelastic scattering and surface roughness, and evaluate the validity of the one-dimensional model presented. (33 refs.)

Proceedings of the XVIII All-Union Conference on Emission Electronics ....See Entry 69775

79.20K Other electron impact phenomena

72904 Scattering of slow electrons by a surface and its relationship to the energy structure. S.A.Komolov (Leningrad State Univ., Leningrad, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.153-7 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1377-82 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Results concerning scattering of slow electrons on the surface of certain metals and semiconductors, using the method of total-current electron spectroscopy, indicate that groups of substances with similar structures of the valence- and free-state densities are characterized by similar experimental spectra. A detailed analysis of the spectra can reveal the structural features of the state density of particular elements, can determine the energy localization of the extrema of free states, and can estimate the contribution of direct and indirect transitions in electron scattering. In addition to features corresponding the bulk structure of the material, the spectra display differences in the structure of the space density of the surface region and features associated with electron transitions involving surface states. (21 refs.)

72905 Wavevector-resolved electron-energy-loss spectroscopy on the dangling-bond states of Si(111)-(2$\times$1). R.Matz, H.Luth, A.Ritz (Phys. Inst., RWTH, Aachen, Aachen, Germany).
Solid State Commun. (USA), vol.46, no.4, p.343-6 (April 1983).
Low-energy-loss spectra of the clean cleaved Si(111)-(2$\times$1) surface with wavevector resolution are discussed. Parallel to the Γ-J line in the surface Brillouin zone large dispersion in the dangling-bond bands is found near the energy gap at the J-K line. This is in contradiction to the formerly accepted buckling model and favours the recently suggested π-bonded chain model for the (2$\times$1) reconstruction. (12 refs.)

72906 Theoretical and experimental studies of multiple thin-film electron scattering. A.N.Pilyankevich, V.M.Vereshchaka, V.N.Ostapenko, V.Yu.Kulikovskii.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.571-4 (April 1983). In Russian.
Considers principles of the spline-approximation method application to a numerical solution of the problem on multiple radiation flux scattering by a substance. Theoretical and experimental characteristics are given for electrons scattered by thin amorphous objects. Theoretical results in terms of the multiple scattering theory are in good agreement with experimental data. It is shown that the single scattering theory may be applied to describing electron scattering only for small objects whose thickness is much less than the length of a free electron path. (6 refs.)

72907 Spatial and energy distributions of incident particles and recoil atoms at finite distances behind a scattering center. L.L.Balashova, A.I.Dodonov, E.S.Mashkova, V.A.Molchanov (Sci. Res. Inst. of Nuclear Phys., Moscow State Univ., Moscow, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.169-74 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1395-400 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Considers the energy and spatial distributions of both scattered particles and of recoil atoms on a plane at a distance D behind the scattering atom, for various ratios of the masses of the incident particles and scattering atom and for various primary-particle energies. Calculations were made within the framework of classical scattering theory. It is shown that the distance from the point of intersection of the asymptotes of the diverging particles to the projection of the initial position of the scattering atom onto the original direction of motion of the incident particles may be comparable not only to the impact parameter but also (in a number of cases) to the interatomic distance. (16 refs.)

72908 Rotational energy distributions in molecule surface scattering: model calculations for NO/Ag(111). J.A.Barker, A.W.Kleyn, D.J.Auerbach (IBM Res. Lab., San Jose, CA, USA).
Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.9-13 (6 May 1983).
Classical trajectory and quantum-mechanical calculations of finite rotational state distributions are described for a simple model of the scattering of NO from Ag(111) which show strong effects of rotational rainbows. The quantum-mechanical calculation reproduces the general trends of the experimental data quite well. The classical calculation is qualitatively and quantitatively inadequate, an inadequacy which is remarkable in view of the large masses of the particles and the high degree of rotational excitation. (11 refs.)

72909 Cluster-ion emission from an aluminium surface under Cd$^+$ ion bombardment. P.Chakraborty, S.D.Dey (Saha Inst. of Nuclear Phys., Calcutta, India).
Int. J. Mass Spectrom. & Ion Phys. (Netherlands), vol.50, no.3, p.349-51 (15 May 1983).
A special feature of secondary-ion mass spectrometry (SIMS) is the liberation of polyatomic particles (clusters), either in the neutral or ionic state, from ion-bombarded solid surfaces by a sputtering process. The cluster yield is much smaller than that of single atoms or ions. Nevertheless, cluster-ion emission has recently been the subject of extreme interest for the wealth of information it contains about the surface. Some experimental data are reported for secondary Al$^+$, Al$_2{}^+$ and Al$_3{}^+$ intensities from a more or less clean polycrystalline aluminium surface as a function of bombarding Cd$^+$ ion energy in the range 3-10 keV for various values of target current density in the range 100-250 μA cm^{-1}. (10 refs.)

72910 Energy dependence of diffraction intensities: ^{4}He+LiF(001). G.Drolshagen, A.Kaufhold, J.P.Toennies (Max-Planck-Inst. fur Stromungsforschung, Gottingen, Germany).
Isr. J. Chem. (Israel), vol.22, no.4, p.283-8 (1982).
The dependence of specular and first order diffraction probabilities on the atom beam energy has been calculated for the system He+LiF(001) in the energy range 18 to 58 meV. A realistic Lennard-Jones-Devonshire atom surface potential with several values of the β-parameter, determining the strength of the corrugated part, was used. A comparison with the predictions of the simple Rayleigh eikonal approximation shows agreement with respect to the overall trends, however the quantal calculations show some deviations and the additional effect of selective adsorption resonances. The results are compared with recent measurements for the $\langle 100 \rangle$ and $\langle 110 \rangle$ directions and good agreement is found for $\beta_{10}=0.086$. (23 refs.)

72911 A study of lineshapes in selective adsorption in atom-surface scattering. V.Celli, D.Evans (Univ. of Virginia, Charlottesville, VA, USA).
Isr. J. Chem. (Israel), vol.22, no.4, p.289-93 (1982).
Calculations are presented involving the scattering of low energy ^{4}He atoms from LiF(001), and compared with experiment. Resonant scattering theory is briefly reviewed, and a prescription for determining the shapes and signatures of resonant features is presented. Inelastic effects are included by means of a Debye-Waller scaling. (8 refs.)

72912 Helium diffraction as a probe of surface structure. T.Engel (Dept. of Chem., Univ. of Washington, Seattle, WA, USA).
Isr. J. Chem. (Israel), vol.22, no.4, p.294-7 (1982).
The diffraction of He atoms from solid surfaces has been recently used to determine the electron distribution of electrons at surfaces. From this, the position of underlying atoms can usually be inferred. Recent developments which test the validity of the hard corrugated wall method to calculate diffraction intensities are discussed. Structural studies which have been carried out to date, on various surfaces with He beams, are tabulated. (46 refs.)

72913 Scattering of N$_2$ from Ag(001). C.W.Muhlhausen, J.A.Serri, J.C.Tully, G.E.Becker, M.J.Cardillo (Bell Labs., Murray Hill, NJ, USA).
Isr. J. Chem. (Israel), vol.22, no.4, p.315-20 (1982).
Experimental and theoretical studies of the scattering of nitrogen molecules from the (001) face of silver are presented. Angular and time-of-flight distributions of the scattered molecules have been measured for incident N$_2$ energies between 7 and 96 kJ/mol, and for surface temperatures between 205 and 600K. Stochastic trajectory simulations have been carried out for the same conditions. Good agreement between experiment and theory has been obtained. The angular distributions are very sensitive to the extent of corrugation of the gas-surface interaction potential, but are relatively insensitive to rotational energy transfer. Scattered velocity distributions also show only a small dependence on rotational energy transfer. (16 refs.)

72914 Quantum-mechanical treatments of rotationally inelastic molecule-surface scattering. D.J.Kouri (Dept. of Chem., Univ. of Houston, Houston, TX, USA), R.B.Gerber.
Isr. J. Chem. (Israel), vol.22, no.4, p.321-8 (1982).
Quantum-mechanical approximation methods and calculations for rotational transitions in molecule-surface collisions are reviewed. The methods are analyzed with regard to predictions of several observable effects: (1) Large ΔJ (rotational quantum number) transitions, and rotational rainbow scattering. (2) The relation between rotational and diffractive transitions. (3) Scaling properties of the rotationally-inelastic scattering amplitudes. (4) Trapping and resonances induced by rotational-translational energy transfer. The methods examined with regard to some of these effects include: coupled-channel calculations; the sudden approximation with regard to both the rotational and the diffractive transitions, and the hard corrugated wall model. It is concluded that whilst available methods provide a qualitative description of the effects mentioned, quantitative treatment of real systems remains an open problem. The main difficulties in formulating a satisfactory quantitative model are examined. Finally, the article presents new results on molecular reorientation processes (ΔM_J transitions) in molecule-surface collisions. It is shown, using the sudden approximation, that molecular reorientation probabilities should reflect sensitively on surface structural corrugation. (41 refs.)

72915 Ion induced surface alterations due to electronic charge exchange and chemical reactions. J.W.Rabalais (Dept. of Chem., Univ. of Houston, Houston, TX, USA).
Isr. J. Chem. (Israel), vol.22, no.4, p.365-74 (1982).
A general discussion of the phenomena that can occur during ion-surface encounters is presented and specific examples of charge exchange processes on LiF surfaces and chemical reactions of N$_2{}^+$ on metals are shown. During rare gas ion bombardment of LiF, ejection of F$^+$ ions and excited Li atoms and the energy distributions of secondary F$^+$ ions can be correlated with Auger primary ion-surface charge exchange transitions determined by the potential energy of the primary ion vacancy and electron promotions resulting from close atomic encounters. Nitridation of Al, Cu, Mo, and Ni to produce very thin nitride surface films is induced by 0-50 eV mass selected N$_2{}^+$ beams. The efficiency of nitridation, monitored by the KL$_2$L$_2$ nitrogen Auger electron signal, exhibits a large kinetic energy E_k dependence below ca. 30 eV. The threshold impact energy for nitridation varies for the different metals; it is nominally zero for Al and Ni, ~4 eV for Mo, probably >0 for Cu, and does not occur at any energy below 200 eV for Ag. That the metal electronic

structure is a critical parameter is evidenced by the facts that different ion doses are required to produce similar nitride signal levels on various metals and that plots of nitride intensity versus E_k exhibit structure or at least different shapes in the low E_k region. A simple quantum mechanical model is used to simulate the nitridation reaction by delineation into four elementary steps: (1) neutralization of incoming N_2^+, (2) decomposition of N_2 into 2N, (3) deexcitation and thermalization of N, and (4) chemical reaction proper. (35 refs.)

72916 An overview of ion sputtering physics and practical implications. J.-C.Pivin (Lab. de Metall. Phys., Univ. Paris-Sud, Orsay, France).
J. Mater. Sci. (GB), vol.18, no.5, p.1267-90 (May 1983).
Surveys the forms of energy exchange between incident ions and target atoms, and the distribution in depth of deposited energy. This analysis is then used to interpret the sputtering yield under various circumstances. A survey is given of the different forms of radiation damage in sputtered targets, with special reference to the many factors that modify the original composition profile: such modification is related to the bombardment conditions used in analytical techniques such as AES, ESCA or SIMS which may be used, inter alia, to determine composition profiles. (101 refs.)

72917 Equilibrium charge states of ^{3}He ions emerging from solid targets at high incident energies. I.Katayama, G.P.A.Berg, W.Hurlimann, S.A.Martin, J.Meissburger, W.Oelert, M.Rogge, J.G.M.Romer, J.L.Tain, B.Styczen (Inst. fur Kernphys., Kernforschungsanlage Julich, Julich, Germany), G.Gaul.
Phys. Rev. A (USA), vol.27, no.5, p.2738-40 (May 1983).
The yield of $^3He^{1+}$ ion produced by a $^3He^{2+}$ beam in C, Al, Ni, Ag, and Au foils was measured at 68, 99, and 130 MeV in order to determine the electron-capture cross sections σ_c. Measurements were performed using targets thicker than 60 $\mu g/cm^2$, where charge equilibrium was found. The results are compared with electron-stripping and -capture theories, which are found to explain fairly well the yield of $^3He^{1+}$. (15 refs.)

72918 Interaction of helium with a metal surface. N.D.Lang (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA), J.K.Norskov.
Phys. Rev. B (USA), vol.27, no.8, p.4612-16 (15 April 1983).
It is shown that the binding of a helium atom to a metal surface is well described using the local-density approximation to treat exchange and correlation effects. The self-consistent solution is in turn well approximated by the effective-medium theory. In this theory the interaction is dominated by a repulsive term proportional to the surface electron density. (17 refs.)

72919 Effect of parallel velocity on charge fraction in ion-surface scattering. J.N.M.van Wunnik (FOM-Inst. for Atomic & Molecular Phys., Amsterdam-Watergraafsmeer, Netherlands), R.Brako, K.Makoshi, D.M.Newns.
Surf. Sci. (Netherlands), vol.126, no.1-3, p.618-23 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The negative charge fraction in proton scattering from Cs-covered W(110) is found experimentally to be a strong function of parallel velocity V as well as perpendicular velocity $v_\perp$ entering in previous theoretical treatments. Theory shows that V may be taken into account by displacing the Fermi sphere in existing theory by $Q=mV$. A simple model and a more complete calculation explain the H^+ data. Extension to the case of Na atomic beams on clean W(110) shows that the V-effect is too small to explain discrepancies between theory and experiment at low T. (11 refs.)

72920 Thermal energy helium scattering from CO/Pt(111) at very low coverages. B.Poelsema, R.L.Palmer, S.T.de Zwart, G.Comsa (Inst. fur Grenzflachenforschung und Vakuumphys., KFA Julich, Julich, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.641-6 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Reports on thermal He scattering from CO/Pt(111) at low coverages ($\theta_{CO}<0.01$), which was shown to be dominated by long-range attractive forces centered at the adsorbed CO molecules. The scattering cross section of adsorbed CO is measured as a function of both the velocity of the incident He atoms and the angle of incidence. To a first approximation, the angular dependencies can be understood in terms of simple geometric 'shadowing like' effects. The velocity dependencies, measured at different angles of incidence, coincide on a universal curve after correction for refractive and geometric effects. (13 refs.)

72921 Simultaneous excitation of rotations and surface phonons in the scattering of D_2 from a NaF crystal. G.Brusdeylins, J.P.Toennies (Max-Planck-Inst. fur Stromungsforschung, Gottingen, Germany).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.647-53 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Angular distributions and time-of-flight spectra have been measured for the scattering of n-D_2 from NaF(001) along the ⟨100⟩ direction at energies between 30 and 90 meV. The angular distributions reveal, in addition to elastic diffraction peaks, additional sharp peaks due to the rotational transitions $0\to1$, $1\to3$, and $0\to4$. The relative rotational transition probabilities show an anomalous behavior which can in part be explained by a kinematic rainbow. An enhancement of rotational transitions in grazing collisions (large θ_i) is also observed. The time of flight spectra confirm the assignments and reveal that phonon processes also are occurring simultaneously with the rotational transitions. (13 refs.)

72922 Enhanced sensitivity of Ne atoms to inelastic scattering by bulk phonons with respect to He/LiF experiments. E.Semerad, E.M.Horl (Inst. fur Metall., Osterreichisches Forschungszentrum Seibersdorf GmbH, Seibersdorf, Austria).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.661-5 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Inelastic scattering of ^{20}Ne atoms from a LiF(001) surface in the ⟨100⟩ azimuth is studied by high resolution time-of-flight measurements. Ne nozzle beams with kinetic energies of 65 and 19 meV and a velocity resolution of $\Delta v/v \sim 0.5\%$ FWHM are used. For both energy regimes, single phonon scattering is found to be the dominant inelastic process. At the present signal-to-noise ratio only interactions of the Ne atoms with acoustic modes can be detected. The major contribution of these interactions is caused by bulk phonons terminating at the surface. The probabilities of the interactions with Rayleigh modes and modes of the acoustic bulk bands show marked differences to He/LiF experiments. (9 refs.)

72923 Quantum model for kinetics of helium atoms near surfaces of free-electron metals. II. Overlap-induced dissipation. B.Gumhalter (Inst. of Phys., Univ. of Zagreb, Zagreb, Yugoslavia), Z.Crljen.
Surf. Sci. (Netherlands), vol.126, no.1-3, p.666-74 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
For pt.I see ibid., vol.117, p.116 (1982). A quantum model developed formerly to describe inelastic collisions of low-energy helium atoms with surfaces of free-electron metals is extended to include the electronically induced dissipative scattering arising from the overlap-induced electron-He atom pseudopotential. It is shown that the repulsive adatom-substrate Hartree-Fock interaction, known to be proportional to the overlap S between the adatom and substrate electronic densities, is succeeded by a series of nonadiabatic higher-order terms which also give rise to dissipative processes in adatom-surface collisions. The leading contribution to this series which contains the information on the decay rate of the adparticle initial state is calculated up to the order S^2 using the formalism of the surface response function developed earlier. Such a formulation does not require the use of any adjustable parameters and the results obtained indicate the importance of this scattering mechanism with respect to the polzarization-induced dissipation discussed in part I. (26 refs.)

72924 Potentials for atom-surface scattering. P.Nordlander (Inst. of Theoretical Phys., Chalmers Univ. of Technol., Goteborg, Sweden).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.675-80 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
Atom-beam scattering experiments, which provide useful information on the surface structure, are now being performed at a level that makes it crucially important to know the atom-surface potential accurately. As an attempt to provide atom-surface scattering potentials that are simple in form, that apply for different atom-surface combinations by just changing some parameters, and that can include lattice effects, a pseudopotential perturbation approach has been proposed. The first-order term agrees within 15% with the result for jellium. Inclusion of the second-order term gives almost complete agreement in the case of He on Al, thus providing a simple and practically useful method to get accurate atom-surface scattering potentials. Application has also been made to the He-Ag and He-Mg systems. (12 refs.)

72925 Atom scattering by soft-potential surfaces with one-Rayleigh-phonon exchange. N.Garcia, J.M.Soler (Dept. de Fisica Fundamental, Univ. Autonoma, Canto Blanco, Madrid, Spain).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.689-94 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
The differential cross sections for atom scattering by surfaces with one-Rayleigh-phonon exchange are calculated using a Debye model for the solid and an exponential potential from the atom-surface interaction. The intensities obtained are considerably lower than those given by a hard wall and depend strongly on the experimental conditions (incident energy and incident and final angles). In some conditions a cut-off appears and this might explain the experimental cut-off observed in Cu(001) and in Ni(111). The Debye-Waller factor effect and the Beeby effect of a well are also calculated and discussed. (8 refs.)

72926 The formation of Ta^+ secondary ions at oxygen-covered Ta surfaces. H.Oechsner, Z.Sroubek (Phys. Inst., Tech. Univ. Clausthal, Clausthal-Zellerfeld, Germany).
Surf. Sci. (Netherlands), vol.127, no.1, p.10-20 (April 1983).
Absolute ionization probabilities R for Ta^+ secondary ions are determined both experimentally from comparative in-situ SNMS and SIMS measurements and theoretically on the basis of recent microscopic ionization theories as a function of the oxygen surface concentration c_O. The theoretically predicted c_O dependence of R for sputtered Ta particles is found to agree well with the experimental results. The comparison between experiment and theory gives quantitative estimates of factors which influence the oxygen induced ion yield enhancement. (19 refs.)

72927 Diffraction of He from Cu(110) in the 20-240 meV range; comparison with a realistic model potential. B.Salanon, G.Armand, J.Perreau, J.Lapujoulade (Service de Phys. des Atomes et des Surfaces, CENS, Gif-sur-Yvette, France).
Surf. Sci. (Netherlands), vol.127, no.1, p.135-52 (April 1983).
The results of the diffraction of helium from Cu(110) are presented in the 21-240 meV energy range. The corrugated Morse potential gives a good fit but its corrugation amplitude increases with incident energy. A new form of potential, the modified corrugated Morse potential, is presented and its main properties are examined. With this potential, a good fit of the experimental results for various incidence angles is obtained; no change of the parameters is necessary in the whole range of incident energies. So one gets a realistic picture of the He/Cu(110) interaction. (9 refs.)

72928 Rotationally mediated selective adsorption in rigid rotor/rigid surface scattering. R.Schinke (Max-Planck-Inst. fur Stromungsforschung, Gottingen, Germany).
Surf. Sci. (Netherlands), vol.127, no.2, p.283-314 (April 1983).
Presents a detailed investigation of a new effect in molecule/surface scattering, rotationally mediated selective adsorption, which has been first observed by Cowin et al. (1981) in rotationally inelastic HD/Pt (111) scattering. It is due to resonance between an asymptotically closed rotational channel and a vibrational bound state of the molecule/surface system. Exact close-coupling and diffractionally sudden calculations are performed for HD scattered from a rigid, flat and weakly corrugated surface. Both variation of the collision energy and variation of the incident angle are considered. In the latter case the author includes the averaging over the collision energy of the initial beam and compares qualitatively the results with experiment. Taking into account the resonances below the $j=0\to1$ threshold he is able to explain all of the experimentally observed resonances and to assign them with the appropriate rotational-vibrational quantum numbers. The largest deviation between experimental and theoretical resonance angles is $\sim1.6°$ at a collision energy of $E=109$ meV. An interesting interference effect is found in the case of weak surface corrugation. Although the diffractionally sudden approximation generally gives only poor results, it also reproduces this effect and provides a simple explanation of it in terms of the Breit-Wigner representation of the S-matrix. (41 refs.)

72929 The effect of oxygen on the sputtering of metastable atoms and ions from Ba metal. D.Grischkowsky, M.L.Yu, A.C.Balant (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
Surf. Sci. (Netherlands), vol.127, no.2, p.315-30 (April 1983).
By means of the Doppler-shift-laser-fluorescence technique the authors have measured the effect of oxygen coverage on the velocity distributions and relative yields of sputtered Ba atoms and ions in both the ground and metastable excited states. The measurements show no evidence that the excitation probabilities are correlated with the magnitude of the electric-dipole-moment

matrix element to the ground state. They also find that the excitation probability of the Ba(^{1}D) state from a clean metal surface depends strongly on the emission velocity ν and approaches the functional form exp $(-A/a\nu)$ at higher velocities. (33 refs.)

72930 Metastable de-excitation and ion neutralization near a surface. C.Boiziau (Service de Phys. des Atomes et des Surfaces, CENS, Gif-sur-Yvette, France).
Scanning Electron Microsc. (USA), pt.3, p.949-59 (1982).
Gives a overall picture of the interaction mechanisms taking place when slow ions or metastable atoms arrive in the close proximity of a solid surface. It is shown that the electronic emission process is essentially governed by the overlapping wave functions of the metastable level of the incident atom (ionized or excited) and the electronic levels of the surface: either the electronic emission is due to an auger neutralization, or it is due to an Auger de-excitation. But in both cases, the electronic energy distribution contains information from the outer part of the solid-vacuum interface; it is also emphasized that no significant modifications are made to the interface itself. On these basis, two spectroscopies are described: INS (Ion Neutralization Spectroscopy) and MDS (Metastable De-excitation Spectroscopy). Experimental results confirm the theoretical predictions. (43 refs.)

72931 Ion-neutralization of multiply charged particles near a surface. P.Varga, W.Hofer, H.Winter (Inst. fur Allgemeine Phys., Tech. Univ. Wien, Wien, Austria).
Scanning Electron Microsc. (USA), pt.3, p.967-71 (1982).
The interaction of slow multiply charged rare gas ions with surfaces was tested by accelerating and decelerating both singly and multiply charged ions. Target current and current of secondary electrons emitted onto a collector were measured in order to determine the electron yield. Retarding grids were used to measure ejected electron-energy distributions. The experiment represents a stepwise neutralization in a sequence of Auger-de-excitation (AD) and Auger-neutralization (AN) processes for doubly charged neon ions. The first neutralization step was found to involve either Resonance neutralization (RN)+AD or AN into excited ion states. Increasing the ion energy caused the characteristic distribution peaks to disappear. Although stepwise neutralization takes place at higher ion energies also, the level broadening smooths any structure that may have originated at the electronic structure of the surface. (10 refs.)

72932 SIMS depth profiling of Cr-Ni multilayer targets. J.Giber, D.Marton, J.Laszlo, A.Hanusovszky, P.Stingeder (Phys. Inst., Tech. Univ., Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.117-20 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Measured depth profiles of multilayer Cr-Ni structures with 15-24 layers of 4-10 nm individual layer thickness are presented. A Balzers SIMS with 3 keV Ar^+ ions was used. Ni^+, Cr^+, NiO^+, CrO^+, $Ni_2{}^+$, $Cr_2{}^+$ and $NiCr^+$ ions were detected in reactive and non-reactive measurements. Starting out from the measured depth profiles, the authors obtained relative depth resolution vs. depth functions by a special definition of the absolute resolution. These measurements show that the SIMS itself is able to give valuable depth resolution functions. The absolute depth resolution can be 1-2 nm in optimal cases. (8 refs.)

72933 Computer simulation of the sputtering-induced composition change in Cu-Au, Cu-Ni and Cu-Pd alloys in the initial period of depth profiling. L.Fustoss, J.Laszlo, J.Giber (Phys. Inst., Tech. Univ., Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.121-4 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
The authors have developed a simulation model for examining the characteristics of the sputtering process of metal targets forming a face-centered cubic lattice. In their model the composition of the metal, the features of the lattice determining the cascade mixing and the interaction potentials can be changed. Also the mass and energy of the bombarding particles can be varied. The changes in the concentration profile for binary alloys can be determined by the registration of the composition change of the atomic layers. The authors can also analyse the dependence of the concentration changes in the topmost few layers on the masses of the component atoms and on their displacement energies. Besides the verification of the tendencies they have compared their calculations with experimental results for Cu-Au, Cu-Ni and Cu-Pd alloys. The experimental trends can be well explained with the authors' model. (31 refs.)

79.40 THERMIONIC EMISSION

72934 Use of ion-scattering spectroscopy for investigating processes on the surface of efficient thermoemitters. A.B.Tolstoguzov, G.N.Shuppe (Ryazan Radioengng. Inst., Ryazan, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.54-6 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1275-7 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors employ ion-scattering spectroscopy to investigate processes on the surface of efficient thermoemitters (ETE). The latter can provide model systems with an element composition of the uppermost atomic layer that varies in relation to the temperature. On the one hand, the work is aimed at clarifying a number of debatable aspects of the ETE mechanism; on the other hand, it was intended to enhance the popularity of the low energy backscattered ion-spectroscopy (LEBSIS) method and to promote its more widespread deployment for scientific and engineering purposes. (9 refs.)

72935 Interaction between thin films of barium and epitaxial crystals of strontium oxide. A.N.Andronov, S.V.Malyshev, N.A.Pronina (Kalinin Leningrad Polytech. Inst., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.129-33 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1352-6 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Auger electron spectroscopy (AES), ionization spectroscopy (IS), total-current spectroscopy (TCS), slow electron diffraction (SED), and contact potential difference (CPD) are employed to investigate the position, structure, and work function of thin layers of barium on the surface of monocrystalline films of strontium oxide. Films were deposited and their properties investigated in an ultra-high-vacuum ($p\sim5\times10^{-8}$ Pa) experimental device equipped with an electron-beam evaporator and a three-grid energy analyzer with a retarding field. The substrates were provided by the (100) and (110) faces of a molybdenum single crystal. (7 refs.)

72936 Some aspects of thermoemission of cathodes based on lanthanum and yttrium oxides. V.I.Podgornyi (Inst. of Radio Engng. & Electronics, Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.190-3 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1416-19 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The authors have shown that holding of cathodes based on Y_2O_3 and La_2O_3 at the activation temperatures for $\tau=2$-3 hr, with subsequent cooling, results in a surface state with enhanced thermoemission activity. They have established that holding of cathodes in an electric field of positive polarity leads to a $\sim$0.35 eV reduction in the thermoemission activity of lanthanum oxide, and to a $\sim$0.05 eV reduction for yttrium oxide, as compared to holding in a field of negative polarity. The effect can be linked to changes in concentration of metal adatoms on the cathode surface. (7 refs.)

72937 Electroforming and electron emission of carbon thin films. H.Araki (Electron Beam Lab., Osaka Univ., Osaka, Japan), O.Hirabaru, T.Hanawa.
J. Vac. Soc. Jpn. (Japan), vol.26, no.1, p.22-9 (1983). In Japanese.
Develops the fabrication techniques of a thin film electron emitter. Devices with good reproducibility and stability were obtained when carbon films were deposited on a Corning 7059 glass rubbed with emery paper (#1000), and were heat-treated at 600°C in high vacuum. When the input power density to the devices attained to about 2.4×10^8 W/cm^3, the carbon films were locally broken due to the joule heating and electron emission from the devices were detected. The *I-V* characteristics after the forming were similar to those of the electroformed MIM type devices, and the emission efficiencies were $(2\sim6)\times10^{-4}$. (7 refs.)

Adsorption of barium on the (110) and (111) faces of molybdenum .... See Entry 72219

79.60 PHOTOEMISSION AND PHOTOELECTRON SPECTRA

72938 Study of morphology and composition of Pt-black catalysts. III. XPS study of Pt-black. Z.Paal, P.Tetenyi (Inst. of Isotopes, Acad. of Sci., Budapest, Hungary), D.Prigge, X.Z.Wang, G.Ertl.
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.307-20 (March 1983).
For pt.II see ibid., vol.14, p.101 (1982-83). Samples of Pt-black reduced in aqueous medium by HCHO and subjected to sintering in hydrogen at different temperatures were studied by XPS. Most of the platinum surface is covered by oxygen and carbon. The presence of small amounts of Si has been confirmed. The ratio of Pt $4f_{7/2}$ to $4f_{5/2}$ peak intensities indicates that a considerable fraction of the surface Pt atoms is in an oxidized state, bound to oxygen and, presumably, also to surface CO. The double O 1 s peak confirms the presence of two types of oxygen (Pt-O and CO, respectively). In situ hydrogenation removes oxygen from Pt-O as well as carbon from PtC_x species, leaving most of the surface CO intact. (34 refs.)

72939 Energy-band structure of copper iodide [photoelectron spectra]. V.K.Adamchuk, G.V.Prudnikova, A.B.Smirnov, Yu.A.Shuba (Leningrad State Univ., Leningrad, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.109-12 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1332-5 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The observed structure of the photoelectron spectra in the region $h\nu\geq10.8$ eV is explained by excitation as a result of direct transitions in the regions of points Γ and X of the Brillouin zone of copper iodide. The authors determined the energies of the flat portions of the valence bands in the region of point X: -1.8; -2.9; -4.3 eV and in the region of point Γ: -0.8 eV. The energies of singular points in the conduction band of copper iodide are, in the region of point X: 6.4; 6.7 eV; in the region of Γ: 9.6 eV. (7 refs.)

72940 Mechanism of escape of photoelectrons from photocathodes with negative electron affinity. A.L.Musatov, V.L.Korotkikh (Inst. of Radio Engng. & Electronics, Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.134-7 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1357-60 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
Photocathodes with negative electron affinity (NEA) are highly doped p-type semiconductors, whose work function is reduced by adsorption of cesium and oxygen in such a way that the vacuum level lies below the bottom of the conduction band in the bulk of the semiconductor. The authors conducted a cycle of studies of the work function and photoelectron spectra of GaAs and GaInAs photocathodes, which yielded new conceptions of the mechanism of

escape of photoelectrons from NEA photocathodes. They present the principal experimental findings obtained in this cycle of studies, and offer a detailed analysis and a new model of photoemission from NEA photocathodes. (15 refs.)

72941 Comparative investigation of the formation of an activating coating of photocathodes based on mono- and polycrystalline gallium arsenide. L.I.Antonova.

Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.138-40 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1361-3 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).

Polycrystalline layers (PL) of gallium arsenide were grown by the gas-phase epitaxial method on molybdenum substrates; epitaxial structures (ES) of gallium arsenide were prepared by the liquid-phase method on monocrystalline gallium arsenide. It is shown that activating coatings cannot be the determining factor in differences in efficiency of emitters based on PL and ES of gallium arsenide. The main factor lies in the structure of these layers itself. Estimates of the diffusion length of minority carriers in the most efficient PL cathodes yield 4-5 μm. Consequently, the minimum dimension of the crystal should in any case be no less than 2L, i.e. 10 μm, something that does not always occur in reality. The size degree of perfection, directional growth, and surface purity of single crystals are the chief factors that foster enhanced photosensitivity of cathodes. (2 refs.)

72942 Screening of electric field and photosensitivity of InSb cathodes. S.I.Baranchuk, N.V.Mileshkina (Leningrad State Univ., Leningrad, USSR).

Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.141-3 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1364-6 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).

The operation of semiconductor field-effect cathodes in the mode of photosensitive emission is determined by the conditions of absence of electric breakdown and screening of the external emission field by the surface region. The authors measure the I-V characteristics of an InSb field-effect cathode and the change in emission after laser illumination. The loss of photosensitivity during operation is investigated by SEM studies of the surface. (7 refs.)

72943 Photostimulated exoemission from some organic compounds. I.V.Krylova, M.Ya.Mel'nikov (Moscow State Univ., Moscow, USSR).

Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.186-9 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1412-15 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).

The authors' approach to phenomena of photostimulated emission from organic compounds, based on simultaneous recording of the photocurrent and of photochemical conversions (e.g. by the EPR method), makes it possible to clarify the mechanism of formation of surface traps under illumination, the mechanism of stabilization of the resultant charges, and the nature of the trap. An approach based on simultaneous investigation of electrical phenomena and the chemical action of charged-particle fluxes has recently been developed for the study of microprocesses of capture of charged carriers in the formation of electrets. (8 refs.)

72944 Dielectric dispersion in optical electron transfer in solution. P.Delahay (Dept. of Chem., New York Univ., New York, NY, USA).

Chem. Phys. Lett. (Netherlands), vol.96, no.6, p.613-18 (29 April 1983).

Dielectric dispersion causes the outer-sphere reorganization free energy to vary with photon energy in optical electron transfer. The resulting distortion of the spectral response for photoelectron emission may yield misleading evidence about the emission yield versus photon energy relationship. Dispersion is taken into account in the calculation of emission threshold energies and the correlation between optical and thermal electron transfer. Results are given for V^{2+}, Cr^{2+}, Mn^{2+}, Fe^{2+}, Co^{2+}, $Fe(CN)_6{}^{4-}$. (23 refs.)

72945 Ionization potentials of 1:1 alternating copolymers containing a pendant carbazolyl group as determined by UV photoelectron spectroscopy. Y.Shirota, Y.Matsumoto, H.Mikawa (Dept. of Appl. Chem., Osaka Univ., Osaka, Japan), K.Seki, H.Inokuchi.

Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.57-9 (6 May 1983).

UV photoelectron spectra of poly(N-vinylcarbazole) (PVCz) and 1:1 alternating copolymers of N-vinylcarbazole in thin films have been measured to determine their threshold ionization potentials ($I_s{}^{th}$). The $I_s{}^{th}$ values of the copolymers are found to be higher than that of PVCz by 0.1 to 0.3 eV. (14 refs.)

72946 The Auger parameter of adsorbed xenon as a probe of surface polarizability. P.C.Stair (Dept. of Chem., Northwestern Univ., Evanston, IL, USA).

Isr. J. Chem. (Israel), vol.22, no.4, p.380-5 (1982).

The change in Auger parameter, α (α=Auger kinetic energy minus photoelectron kinetic energy from core levels) between gas phase and adsorbed phase xenon provides an unambiguous measure of final state electronic relaxation in the surface toward the xenon ion. For many surfaces this relaxation is purely electronic polarization in the surface so that the Auger parameter provides a measure of the surface polarizability. Moreover, the Auger parameter for adsorbed xenon can be related to the relaxation energy in core level photoemission with high accuracy. Measurement of the xenon Auger parameter and its sensitivity to surface dielectric properties is illustrated by experiments on a series of oxygen treated Mo(100) surfaces. (29 refs.)

72947 A study of the core level electrons in iron and its three oxides by means of X-ray photoelectron spectroscopy. P.Mills, J.L.Sullivan (Dept. of Phys., Univ. of Aston, Birmingham, England).

J. Phys. D (GB), vol.16, no.5, p.723-32 (14 May 1983).

The core level electrons in iron and its three oxides FeO, Fe_3O_4 and α-Fe_2O_3 have been studied by means of X-ray photoelectron spectroscopy. The main features of the spectra have been identified and electron binding energies have been measured. The Fe 2p peaks of the oxide spectra are broadened (FWHM$\sim$4.5 eV) due to unresolved multiplet splitting, and shake-up satellites can be observed for both Fe^{II} and Fe^{III} species. For all the samples studied the O 1s spectra consist of two overlapping peaks, one due to the oxide and a higher binding energy peak due to an adsorbed species. The higher binding energy peak was frequently dominant indicating a high degree of absorption on the oxide surfaces. The effect of argon ion etching on the surfaces has also been investigated and the results indicate that the analysis of surfaces by means of ion etching in conjunction with XPS can give misleading results. (9 refs.)

72948 Observation of spin-split electronic states in solids by energy-, angle-, and spin-resolved photoemission. R.Raue, H.Hopster, R.Clauberg (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany).

Phys. Rev. Lett. (USA), vol.50, no.20, p.1623-6 (16 May 1983).

The combination of high energy and angle resolution (100 meV, ±3°) with spin analysis in photoemission spectroscopy is shown to allow the direct observation of magnetically spin-split electronic states. This is demonstrated for normal emission from Ni(110) with polarised Ne I radiation ($h\nu$=16.85 eV). It is found that Δ_{ex}=0.18 eV for the exchange splitting of the S_4 band at the X point in good agreement with a band-structure and photo-emission calculation that considers the self-energy correction explicitly. (16 refs.)

72949 Evidence for interference between direct and inner-shell-deexcitation photoemission in semiconductors. K.L.I.Kobayashi (Optoelectronics Joint Res. Lab., Kawasaki, Japan), H.Diamon, N.Watanabe, M.Taniguchi, S.Suga, H.Nakashima, Y.Murata.

Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.57-9 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).

Photoemission study of Si(111), GaAs(110), and InSb(110) cleaved surfaces is performed in the photon energy range from 30 eV to 130 eV using synchrotron radiation. Anomalous intensity variation with strong line shape modulation is observed in the vicinity of Si 2p, As 3d, and Sb 4d core excitation threshold. The present results are interpreted to be due to interference between direct valence band emission and inner shell deexcitation. Many body effects are found to manifest in the inner shell excitation regime in these wide valence band semiconductors. (13 refs.)

72950 A study of the valence band structure of $Ga_{0.47}In_{0.53}As$ by angle resolved photoemission. J.E.Rowe, T.P.Pearsall, R.A.Logan (Bell Labs., Murray Hill, NJ, USA).

Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.347-9 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).

Angle-resolved ultraviolet photoemission has been used to determine the E-k dispersion along the [$1\bar{1}0$] direction of the surface Brillouin zone. The experimental results indicate that the upper-most valence band in $Ga_{0.47}In_{0.53}As$ is somewhat more flat along [$1\bar{1}0$] than a virtual-crystal model band structure would suggest. The quasi one-dimensional density of states measured along the [111] direction indicates that the L_3 minimum occurs at -1.60 eV below the valence band edge. (9 refs.)

72951 Study of III-V semiconductor band structure by synchrotron photoemission. G.P.Williams, F.Cerrina, J.Anderson, G.J.Lapeyre, R.J.Smith, J.Hermanson, J.A.Knapp (Dept. of Phys., Montana State Univ., Bozeman, MT, USA).

Physica B & C (Netherlands), vol.117-118 B+C, pt.1, p.350-2 (March 1983). (Proceedings of the 16th International Conference on the Physics of Semiconductors, Montpellier, France, 6-10 Sept. 1982).

Angle-resolved synchrotron photoemission studies of six III-V semiconductors have been carried out. For emission normal to the (110) plane of these materials, peaks in the experimental spectra were identified with the bands involved in the transitions, and the critical point energies X_3, X_5, and $\Sigma_1{}^{min}$, were determined. The data indicate that $k_\perp$ is conserved in the transitions. Comparison of the data with theoretical bands permits an evaluation of $k_\perp$ associated with the experimentally observed transition, and from this information the bands were plotted out. (4 refs.)

72952 Site determination for palladium on niobium using angle-resolved photoemission. M.El-Batanouny, M.Strongin, G.P.Williams (Brookhaven Nat. Lab., Upton, NY, USA).

Phys. Rev. B (USA), vol.27, no.8, p.4580-5 (15 April 1983).

The authors demonstrate the possibility of using angle-resolved photoemission from valence levels to gain overlayer site geometry information. To do this they utilize and discuss polarization effects and photoexcitation cross-section effects (as a function of the photon energy). To illustrate the application of the technique they have studied Pd overlayers on Nb(110) and conclude that the Pd(110) overlayer has a hollow-site geometry. (11 refs.)

72953 Photoelectron-diffraction analysis of the structure of c(2×2)O on Ni(001). S.Y.Tong (Dept. of Phys., Univ. of Wisconsin, Milwaukee, WI, USA), W.M.Kang, D.H.Rosenblatt, J.G.Tobin, D.A.Shirley.

Phys. Rev. B (USA), vol.27, no.8, p.4632-6 (15 April 1983).

Calculated energy-dependent photoelectron-diffraction (EDPD) curves for oxygen-nickel perpendicular spacings ($d_\perp$) between 0.0 and 1.2 Å are presented and compared with experimental data for the c(2×2)O-Ni(001) system. Using a normalized R factor, the authors found that only acceptable agreement is for $d_\perp$ spacings in the range 0.78-0.90 Å. The experimental observations that adsorbate-induced modulations remains strong over a wide energy range in EDPD curves, but not in low-energy electron-diffraction intensity curves, is explained. (18 refs.)

72954 Calculation of spin-polarized threshold photoemission from the Ni(001), Ni(111), and Ni(110) surfaces. R.Clauberg (Inst. fur Festkorperforschung, KFA Julich GmbH, Julich, Germany).

Phys. Rev. B (USA), vol.27, no.8, p.4644-53 (15 April 1983).

Calculations of spin-polarized threshold-photoemission spectra of Ni(001), Ni(111), and Ni(110) surfaces are presented, obtained with a one-step model of the photoemission process. As in the previous work of Moore and Pendry (1978), good agreement with the angle-integrated experimental results for emission from the (001) and (111) surfaces is obtained within a normal-emission approximation. In contrast, for emission from the (110) surface it is found that the angle-integrated spectra are dominated by nonnormal-emission contributions. In addition, the influences of relativistic dipole selection rules and surface-state emission on the spin polarization from the (110) surface are discussed briefly. (30 refs.)

72955 Angle-resolved photoemission studies of GaAs(100) surfaces grown by molecular-beam epitaxy. T.-C.Chiang (Dept. of Phys., Univ. of Illinois, Urbana, IL, USA), R.Ludeke, M.Aono, G.Landgren, F.J.Himpsel, D.E.Eastman.

Phys. Rev. B (USA), vol.27, no.8, p.4770-8 (15 April 1983).

Angle-resolved photoemission techniques were used to study GaAs(100) surfaces grown by molecular-beam epitaxy. Three well-ordered surfaces with the c(4×4), c(2×8), and c(6×4) reconstructed surface structures and a disordered As-covered (1×1) surface were investigated in the photon-energy range of 12-70 eV. All major sharp peaks in the normal-emission spectra were found to be transitions from bulk valence bands; therefore, transitions due to surface states were either weak or broad. The variations in bulk-peak intensities for different surface structures were related to surface diffraction effects For photon energies greater than about 20 eV, primary-cone peaks for transitions from the upper bulk valence bands to a broadened and shifted free-electron-like final band were identified, and energy dispersion relations for the upper valence bands were determined along the [100] direction. Surface umklapp transitions were quite strong due to the presence of many short surface reciprocal-lattice vectors. To characterize these surfaces, angle-integrated photoemission measurements of valence bands and core levels were made, and the positions of the Fermi level for these surfaces were detemined. (17 refs.)

72956 X-ray photoelectron spectra of the spinel systems $\mathrm{CdCr_xIn_{2-x}S_4}$ and $\mathrm{ZnCr_xAl_{2-x}S_4}$. C.Battistoni, E.Paparazzo (CNR, Rome, Italy), Y.Dumond, M.Nogues.

Solid State Commun. (USA), vol.46, no.4, p.333-6 (April 1983).

XPS spectra of $\mathrm{CdCr_xIn_{2-x}}S_4$ and $\mathrm{ZnCr_xAl_{2-x}}S_4$ spinel solid solutions are reported. A nearly constant electron density is found over all atomic sites in both series in the whole range of concentration x; this situation is related to covalency. Some interesting features in the Cr3*s* multiplet splitting are discussed. (16 refs.)

72957 Adsorbate-induced umklapp processes in photoemission from Cl on Cu. D.Westphal, A.Goldmann (Lab. fur Festkorperphys., Univ. GH Duisburg, Duisburg, Germany).

Surf. Sci. (Netherlands), vol.126, no.1-3, p.253-7 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).

The authors have studied high-resolution angle-resolved photoemission from Cu(001)-c(2×2)-Cl, Cu(111) $(\sqrt{3}\times\sqrt{3})$R30°-Cl and the clean substrates. Drastic changes of spectral features which occur after adsorption in the energy region of the substrate d-band emission are clearly identified as surface umklapp processes involving reciprocal lattice vectors of the adsorbate. They discuss some implications of their results for the interpretation of angle-resolved photoemission adsorbate studies. (9 refs.)

72958 Photoemission from low-dimensional systems. C.Binns, C.Norris, G.C.Smith, H.A.Padmore (Dept. of Phys., Univ. of Leicester, Leicester, England), M.G.Barthes-Labrousse.

Surf. Sci. (Netherlands), vol.126, no.1-3, p.258-64 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).

The variety of monolayer and submonolayer structures which characterize metallic overlayers supported on single crystal metal substrates offers a valuable opportunity to observe the influence of reduced dimensionality on the electronic states. The authors report results for several systems which illustrate this. (13 refs.)

72959 Photoelectron spectroscopic studies of the adsorption geometry on Ni single crystals: p(2×2), c(2×2) overlayers on Ni(100) and (2×1) symmetry on Ni(110). C.Benndorf, C.Nobl, F.Thieme (Inst. fur Phys. Chem., Univ. Hamburg, Hamburg, Germany).

Surf. Sci. (Netherlands), vol.126, no.1-3, p.265-72 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).

The oxygen induced p(2×2) and c(2×2) LEED symmetries on Ni(100) were studied with UPS He I (s- and p-polarization), He II and XPS (O 1s and XAES O(KLL) spectra), revealing only some minor differences between both states. In the UPS He II analyzed under a polar angle of 45° in the [100] azimuthal direction, the half width of the O 2p maximum from the c(2×2) overlayer increases to $\Delta E=2.5$ eV, suggested to be due to a splitting of the 2p levels. During the transition from p(2×2) to c(2×2), with XPS, only a small increase of the O 1s BE from 529.9 to 530.1 eV is observed, whereas the X-ray excited $\mathrm{O(KL_{23}L_{23})}$ peak shifted from 514.3 to 515.0 eV. In contrast to the results from the p(2×2) and c(2×2) overlayers on Ni(100), where the O 2p intensity nearly vanishes with s-polarization, the O 2p emission from the (2×1) structure on Ni(110) is found to be less dependent from the polarization, The O 2p intensity profile, measured as a function of polar angle in the [100] and [110] azimuthal direction, is nearly identical in both cases. (12 refs.)

72960 Symmetry effects in the electron spectroscopy of metals with an ordered adsorbate overlayer. N.V.Richardson (Donnan Labs., Univ. of Liverpool, Liverpool, England).

Surf. Sci. (Netherlands), vol.126, no.1-3, p.337-48 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).

The influence which an adsorbate may have on the dipole activity of substrate based electron and phonon excitations is discussed. The presence of ordered adsorbate overlayers gives rise to new substrate phonons in specular EELS experiments and new substrate features in photoemission. More importantly, the appearance of these features is shown to be directly related to the particular adsorption site which is occupied. The p(2×2) and c(2×2) overlayers on square lattices as well as $(\sqrt{3}\times\sqrt{3})$R30° and p(2×2) overlayers on hexagonal lattices are considered in some detail. Examples are provided by photoemission results for c(2×2)-Br/Cu(001) and by various EELS studies by Andersson and Persson (1981), and by Ibach and Bruchmann (1980). (15 refs.)

72961 Photoemission study of oxygen adsorbed on coldly deposited silver films. J.Eickmans, A.Goldmann, A.Otto (Phys. Inst. III, Univ. Dusseldorf, Dusseldorf, Germany).

Surf. Sci. (Netherlands), vol.127, no.1, p.153-64 (April 1983).

UPS of coldly deposited silver films differ from those of films deposited at room temperature by electronic states localized at surface defects with an energy about 4.2 eV below E_F. Changes after exposure at 140K to oxygen only occur in the presence of these defects, demonstrating that oxygen is only adsorbed at defects. Raman vibrational spectroscopy shows that oxygen is adsorbed nominally at $\mathrm{O_2^{-}}$ and $\mathrm{O_2^{2-}}$. Possible assignments of the oxygen related UPS structures are discussed. (44 refs.)

72962 Lineshape studies of the X-ray photoemission of small metal clusters. T.T.P.Cheung (Phillips Res. Center, Phillips Petroleum Co., Bartlesville, OK, USA).

Surf. Sci. (Netherlands), vol.127, no.2, p.L129-34 (April 1983).

It is shown that the lineshape asymmetry of the X-ray photoelectron spectra of the Pt(4f) and Pd(3d) core-levels in small clusters decreases with the size of the cluster. Such changes are related to the changes of the density of states of the valence electrons and the effective core-hole potential at the Fermi level. The decrease of the asymmetry leads to a shift of the line position toward a higher binding energy (about half of the observed shift) as governed by the first moment rule. (12 refs.)

72963 XPS investigation of stainless steel surfaces heated in aqueous media. L.Kover, I.Kadar, I.Cserny, J.Toth (Inst. of Nuclear Res., Hungarian Acad. of Sci., Debrecen, Hungary).

Vacuum (GB), vol.33, no.1-2, p.99-105 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).

X-ray photoelectron spectroscopy combined with argon ion etching was used for the investigation of the structure of the oxide layers developed on stainless steel surfaces having been exposed to ion-free water of different temperatures. Photoelectron intensity ratios measured as a function of the ion etching time give information on the composition and depth structure of the oxide layer as well as of the uppermost layers of the alloy. Stainless steel samples of three different types were exposed to the effect of ion and oxygen free water at 20°C and 250°C. In the case of the low temperature (20°C) environment a ~3 nm thick oxide layer could be observed, while the oxide layers developed at high (250°C) temperature treatment were thicker than 8 nm. Samples of the three alloys showed very different chromium enrichment in the oxide layer and chromium depletion in the uppermost layer of the bulk. Results obtained make it possible to follow the effect of a given corrosive environment on the surface, and help to select the proper alloy for this environment. (23 refs.)

72964 Azimuthal X-ray photoelectron diffraction from adsorbate core levels. P.J.Orders, C.S.Fadley, R.Trehan, B.Sinkovic (Dept. of Chem., Univ. of Hawaii, Honolulu, HI, USA), Z.Hussain, J.Lecante.

Fifteenth Annual Synchrotron Radiation Users Group Conference (papers in summary form only received), Stoughton, WI, USA, 18-19 Oct. 1982 (Stoughton, WI, USA: Synchrotron Radiat. Center 1982), p.37-8

X-ray photoelectron diffraction (XPD) associated with core-level emission shows considerable promise as a surface structural probe. Prior studies utilizing standard unpolarized X-ray sources at $h\nu\approx1.5$ keV exhibit considerable fine structure and overall anisotropies $\Delta I/I_{max}$ of up to ~40%. Such data often show strong forward scattering effects that can provide information on bond directions between two surface atoms, and it is also found that azimuthal scans can be analyzed in terms of a very simple single-scattering cluster model so as to yield bonding sites and bond distances for chemisorbed species. All prior work in this area has involved unpolarized sources and relatively high photoelectron energies of $\sim10^3$ eV. This study represents a first exploration of azimuthal XPD with synchrotron radiation. The JUMBO monochromator and a VG ADES 400 photoelectron spectrometer were used to carry out the measurements. (5 refs.)

72965 Angle-resolved photoemission studies of the CdS band structure. N.G.Stoffel, G.Margaritondo (Dept. of Phys., Univ. of Wisconsin, Madison, WI, USA).

Fifteenth Annual Synchrotron Radiation Users Group Conference (papers in summary form only received), Stoughton, WI, USA, 18-19 Oct. 1982 (Stoughton, WI, USA: Synchrotron Radiat. Center 1982), p.49

The authors present the first angle-resolved photoemission study of the band structure of a II-VI compound. The electronic states of wurtzite CdS have been mapped using synchrotron radiation in the 7-35 eV range. By employing both normal and off-normal detection geometries, energies for the upper valence band have been determined for high-symmetry points in the Brillouin zone. Polarization selection rules have greatly facilitated the interpretation of the spectra. Comparison with the results show that the existing calculations predict the correct relative positions of the critical points, but consistently underestimate the dispersion of the valence bands by about 35%. The Cd4d 'core levels' lie within the valence band and exhibit dispersion and an additional split-off low binding energy peak. This is interpreted as a bulk band structure effect as opposed to a surface shift. Furthermore, crystal-field splitting alone cannot account for this effect. Therefore, the Cd4d levels should be taken into account in any realistic band structure calculations. (no refs.)

72966 Angle-resolved energy-dependent photoelectron-diffraction of c(2×2) O-Ni(001): a surface structural determination. S.Y.Tong, W.M.Kang (Lab. for Surface Studies, Univ. of Wisconsin, Milwaukee, WI, USA), D.H.Rosenblatt, J.G.Tobin, D.A.Shirley.

Fifteenth Annual Synchrotron Radiation Users Group Conference (papers in summary form only received), Stoughton, WI, USA, 18-19 Oct. 1982 (Stoughton, WI, USA: Synchrotron Radiat. Center 1982), p.53

The c(2×2) and p(2×2) O on Ni(001) systems have been studied by many surface techniques to determine the binding distance of O on nickel. The authors have analyzed the c(2×2) O-Ni(001) system by angle-resolved energy-dependent photoelectron diffraction (EDPD). They calculate EDPD curves by varying the O-Ni spacing from 0 Å to 1.3 Å in steps of 0.05 Å. After comparison with measured EDPD data, they find good agreement at $d_\perp=0.85$ Å and poor agreement in the range $0.0\leq d_\perp\leq0.3$ Å. (no refs.)

72967 Photoemission and photoabsorption of amorphous Si films. D.Wesner, W.Eberhardt (Brookhaven Nat. Lab., Upton, NY, USA).

Fifteenth Annual Synchrotron Radiation Users Group Conference (papers in summary form only received), Stoughton, WI, USA, 18-19 Oct. 1982 (Stoughton, WI, USA: Synchrotron Radiat. Center 1982), p.54-5

The authors have studied the photoemission and photoabsorption (yield) of in situ sputtered amorphous Si films having various hydrogen content between 0 and 40%. These materials are of technological interest in the production of solar cells. Especially important are the behavior of the bandgap and possible states within the gap as a function of sample preparation (hydrogen content or annealing temperature). (2 refs.)

72968 The problem of cerium. D.Wieliczka (Iowa State Univ., Ames, IA, USA).

Fifteenth Annual Synchrotron Radiation Users Group Conference (papers in summary form only received), Stoughton, WI, USA, 18-19 Oct. 1982 (Stoughton, WI, USA: Synchrotron Radiat. Center 1982), p.56-7

In an attempt to understand the γ-α phase transition photoemission experiments were performed on both γ- and α-Ce. The samples were thick films evaporated in situ from high purity cerium. The γ-phase was produced by evaporating onto a room temperature substrate; the α-phase was formed by evaporating onto a substrate held at ~50K by a closed cycle helium refrigerator. The valence band spectra were measured at photon energies from $20\leq h\nu\leq170$ eV. (no refs.)

79.70 FIELD EMISSION AND FIELD IONIZATION

72969 Explosive emission of metal points cooled to ultralow temperatures. V.M.Zhukov, M.S.Aksenov, G.N.Fursei, N.F.Fedorov.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.88-92 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1310-14 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
When some limiting current density is attained, field emission (FE) becomes explosive emission (EE). The authors' studies have employed points of tungsten (radii 0.2-0.4 μm) and niobium (radii 0.4-0.6 μm) with a rectangular voltage pulse width (τ_p) of 10, 20, and 150 nsec. A number of experiments were conducted using step-shaped voltage pulses. The procedure also provided for the possibility of creating a uniform magnetic field with a strength up to 4 kOe in the tip-anode gap. Microphotographs of tips, obtained with an electron microscope, were used to determine the quantity of material that was transported in the EE process. The relative error in measuring the mass amounted to 25%. (13 refs.)

72970 Some aspects of the control of the current of a high-brightness plasma emitter. V.A.Gruzdev, N.G.Rempe (Tomsk Inst. of Automatic Control Systems & Electronics, Tomsk, USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.102-4 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1324-7 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
In plasma electron sources (PES), the emission current is usually controlled by varying the density, through adjustment of the discharge current used to generate the plasma in the PES. The brightness of the PES depends on the emission current and is usually not great at low current values. In principle, however, it is possible to have another method of control such that the emission current is varied by varying the area of the emitting surface of the plasma. To realize this possibility, the authors utilize the familiar procedure of limiting the emitting surface of the plasma in the PES emission channel by a layer of space charge between the plasma and the channel walls. Here it can be assumed that as the extent of the space-charge layer is varied while the discharge current (emission current density) is maintained constant, it is possible to regulate the emission current without substantially affecting the brightness or stability of PES operation. This method of emission-current control is effective in PES in which the extent of the space-charge layer is comparable to the dimensions of the emission channel. Such sources include, in particular, high-brightness PES based on a reflecting discharge in a magnetic field with a cold hollow cathode and extraction of electrons from the part of the discharge adjacent to the cathode, where the emitting surface of the plasma is confined by the ion layer of space charge in the region of the cathode potential drop. 79.75 EXOELECTRON EMISSION

72971 Aspects of the formation of energy spectra of exoelectrons of thermally stimulated exoemission of dielectrics. V.S.Kortov, V.G.Isakov (Kirov Urals Polytech. Inst., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.175-80 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1401-6 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
By using an improved physical model and algorithm for the energy distribution of exoemission electrons, the authors have substantiated the anisotropic nature of TSEE of NaCl crystals with differing orientation of the planes, and also the fact that the parameters of the electron energy distribution depend on the excitation conditions of the crystal. The dependence of the TSEE on the emitter thickness, together with the obtained crystallographic anisotropy of its parameters, demonstrate that in a high vacuum the TSEE of dielectrics excited by electrons with energies of 1-3 keV is governed by bulk centers. (9 refs.)

72972 Hole-induced exoelectronic emission. B.A.Sorkin, V.V.Bichevin, H.F.Kaambre (Inst. of Phys., Acad. of Sci., Estonian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.181-5 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1407-11 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
By using a variety of experimental procedures, in particular the method of selective optical filling of the hole-capture or electron-capture level, the authors have demonstrated hole-induced exoelectronic emission (HI EEE) in a variety of alkali halides and oxides. It is most probable that HI EEE is effected via intercenter Auger processes, with the involvement (in addition to hole centers) of both two-electron and single-electron color centers. The predominance of the contribution of particular schemes of Auger processes to HI EEE depends greatly on both the particular emitter (in particular, doping impurities) and on the experimental conditions (particularly the preliminary excitation dose). (12 refs.)

81.00 MATERIALS SCIENCE

72973 The influence of English terminology used in powder metallurgy on terms formation in the same field, expressed in other languages. S.M.Radic (Inst. of Tech. Sci., Serbian Acad. of Sci. & Arts, Beograd, Yugoslavia).
Sintering - Theory and Practice. Proceedings of the 5th International Round Table Conference on Sintering, Portoroz, Yugoslavia, 7-10 Sept. 1981 (Amsterdam, Netherlands: Elsevier 1982), p.637-40
Very close contacts between scientists, as well as frequent exchanges of information, have led to new ideas in a certain scientific field quickly circulating and spreading out; a lack of words describing such idea and terms in one language allows the foreign expressions to be accepted and used. In this century of scientific-technical revolution, it has been the English language that has had the most influence on other languages, as most discoveries and achievements have been formulated in it and most publications have been published in English. The influence of English terminology used in powder metallurgy on terms formation in the same field, expressed in other languages with particular review of the Slavonic languages, is presented. It has also been established there that certain English expressions and terms have acquired international meaning. (4 refs.)

81.10B Growth from vapour

72975 Observation of defects in mercury cadmium telluride crystals grown by chemical vapor transport. E.A.Irene, E.Tierney (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA), H.Wiedemeier, D.Chandra.
Appl. Phys. Lett. (USA), vol.42, no.8, p.710-12 (15 April 1983).
A mixture of nitric and hydrochloric acids was found to yield etch pits on mercury cadmium telluride crystals grown by chemical vapor transport using iodine or mercuric iodide as the transport agent. Two types of pits were observed by optical microscopy: triangular pyramidal and round saucer shaped pits. Transmission electron microscopy confirmed that two types of defects were present: dislocations and second phase occlusions. The present study suggests that the defects are near the crystal surface and therefore will probably not significantly affect the electrical characteristics. (8 refs.)

72976 Horizontal vapor transport process of $Pb_{1-x}Sn_xTe$ in a closed tube. Yuan Shi-xin, Xie Qin-xi, Si Cheng-cai, Yu Mei-fang (Shanghai Inst. of Tech. Phys., Acad. Sinica, Shanghai, China).
Chin. Phys. (USA), vol.3, no.1, p.173-9 (Jan.-March 1983). [received: May 1983]
The horizontal vapor transport rate in a closed tube loaded with $Pb_{1-x}Sn_xTe$ can be rapidly measured by a balance method. The effects of the residual gases, such as oxygen, nitrogen, excessive tellurium, and lead on the transport rate are studied. It is shown that in the transport process of sublimate type materials, no saturation appears when the temperature difference is lower than 30°C. The transport equation of the sublimate type is established; the calculated results are compared with the experimental data. According to the data of the transport rate, calculation can be made showing that the interdiffusion coefficient between N_2 and $Pb_{1-x}Sn_xTe$ is 0.013 cm^2/sec. (15 refs.)

72977 The chemical transport of scandium(III)-fluoride by means of silicon tetrachloride and germanium tetrachloride. W.Redlich, T.Petzel (Inst. fur Werkstofftech., Hochschule der Bundeswehr Hamburg, Hamburg, Germany).
Rev. Chim. Miner. (France), vol.20, no.1, p.54-9 (1983). In German.
It is shown that ScF_3 can be chemically transported in a temperature gradient (e.g.: $900°C \rightarrow 850°C$) by means of $SiCl_4(g)$ and $GeCl_4(g)$ in closed quartz ampoules. The transported material is deposited in well-shaped, transparent, colorless single crystals (cubic, space group $Pm3m$, $a = 4.0127 \pm 0.0016$ Å). Observed and calculated transport rates are critically compared considering the following possibly important transport reactions:
$ScF_3(s) + 0.75MCl_4(g) \leftrightharpoons ScCl_3(g) + 0.75MF_4(g)$,
$2ScF_3(s) + 1.5MCl_4(g) \leftrightharpoons Sc_2Cl_6(g) + 1.5\ MF_4(g)$(M=Si, Ge). (20 refs.)

81.10D Growth from solutions

72978 Lattice disorder and electrical conductivity of flux-grown $Ca(WO_4)_x(MoO_4)_{1-x}$ crystals. S.K.Arora, R.S.Godbole, D.Lakshminarayana (Dept. of Phys., Sardar Patel Univ., Gujarat, India).
J. Mater. Sci. (GB), vol.18, no.5, p.1359-64 (May 1983).
The growth of solid solutions of $Ca(WO_4)_x(MoO_4)_{1-x}$ in the range $x = 0.072$ to 0.86 has been successfully accomplished for the first time, employing a flux technique. The fact that proper mixing occurs is established by observing the variation in unit cell parameters and density of the crystals. The electrical conductivity of the pelletized samples is interpreted in terms of Schottky and

Frenkel defect concentrations. The role of oxygen ion vacancies is stressed for the intrinsic region of conductivity. (16 refs.)

72979 Crystal growth of refractory compounds from solutions in metallic melts. V.N.Gurin, M.M.Korsukova (A.F. Ioffe Phys.-Tech. Inst., Acad. of Sci., Leningrad, USSR).
Prog. Cryst. Growth & Charact. (GB), vol.6, no.1, p.59-101 (1983).
The authors present and illustrate the fundamentals of crystal growth of refractory compounds by the solution method. Single crystals of refractory compounds prepared by the solution method have recently been employed for electronic applications. (175 refs.)

72980 Preparation and properties of SmB_6 and SmB_4 single crystals. S.Okada, T.Atoda (Dept. of Appl. Chem., Kanagawa Univ., Yokohama-shi, Japan).
Yogyo-Kyokai-Shi (Japan), vol.91, no.3, p.137-47 (1983). In Japanese.
The preparation of single crystals of SmB_6 (cubic system) and SmB_4 (tetragonal system) using molten aluminum flux method in an argon atmosphere has been investigated. As-grown SmB_6 and SmB_4 single crystals were both used for measurements of lattice constant, density and Knoop-microhardness, and also for the study of oxidation reaction and kinetics in air at temperature range between 700°C and 1250°C and time between 10 and 120 min. (29 refs.)

72981 Temperature fields in apparatus for growing leucosapphire single crystals by using mathematical modeling. Yu.K.Lingart, Ya.I.Shtipel'man (All-Union Sci.-Res. Planning, Design & Technol. Inst. of Electrothermal Equipment, Moscow, USSR).
J. Eng. Phys. (USA), vol.43, no.2, p.936-43 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.306-14 (Aug. 1982). [received: April 1983]
An approximate mathematical model and methodology for designing a horizontal directional crystallization (HDC) apparatus are proposed. The results of computations are compared with experimental data. (11 refs.)

72982 Growth of dislocation-free bulk silicon crystals. R.K.Bagai, W.N.Borle (Solid State Phys. Lab., Delhi, India).
Prog. Cryst. Growth & Charact. (GB), vol.6, no.1, p.25-46 (1983).
This review discusses (a) various known methods for the growth of silicon crystals from the melt and (b) the mechanisms of the formation and the techniques for the elimination of dislocations during growth. (81 refs.)

72983 Silicon sheet technologies. T.F.Ciszek (Solar Energy Res. Inst., Golden, CO, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.316-26
A classification of silicon sheet growth methods by meniscus geometry permits them to be discussed in three groups: short meniscus techniques, high meniscus techniques, and extended meniscus or large solid/liquid interface area techniques. A second parameter, meniscus shaper interaction with the liquid silicon, is also instrumental in determining the characteristics of the various sheet processes. The current status of each process is discussed in the context of meniscus geometry and shaper/melt interaction. One aspect of sheet growth, surface area generation rate, is quantitatively compared with combined ingot growth and wafering surface area generation rates. (43 refs.)

72984 Crystal defect problems. G.H.Schwuttke.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.327-32
A minority carrier lifetime evaluation of 100 mm Czochralski silicon wafers is presented. The evaluation uses wafers as available from major vendors in the world. It relies on minority carrier lifetime mapping of the total wafer area. Main results include local variations of lifetime on a wafer of several orders of magnitude and uncontrollable degradation during hot processing. A similar evaluation of silicon web dendrite shows significant uniform improvement of lifetime over large web areas. The results are related to the defect structures present in both crystal types. (4 refs.)

72985 Advances in the automation of the Czochralski process for silicon crystals. H.Birck (Leybold-Heraeus GmbH, Hanau, Germany).
Semiconductor International '82, England, 1982 (Luton, Beds., England: Benn Electronics Publications 1982), p.25-8
By employing computers and suitable cameras as optical measuring systems it is now possible to automate the pull process completely, especially melting of even large silicon masses, stabilizing of the melt temperature, dipping of the seed into the melt, pulling of neck, shoulder and tail. Applying new pulling technologies such as periodical speed/time functions for the crucible rotation or pulling with varying melt levels are made easy by using a computer. Interfacing of a camera system to a computer allows retrieving of a lot of different data during various process states. Perspective image defects in measuring the crystal diameter can be corrected by the computer by applying the optical projection laws. The result is an accurate diameter measuring system for a wide range of distances between camera and crystal. Online and offline diagnostic routines and test run capabilities of the software ease the maintenance and increase the availability of such highly automated tools, enhancing even more the advances which could be reached by computerizing Czochralski pullers. 72987 Formation of metastable monoclinic rare earth sesquioxides from the melt. R.McPherson (Dept. of Materials Engng., Monash Univ., Clayton, Victoria, Australia).
J. Mater. Sci. (GB), vol.18, no.5, p.1341-5 (May 1983).
A number of rare earth sesquioxides prepared by rapid cooling of the melt, by plasma spraying onto a cold substrate, consist entirely of the metastable monoclinic (B) form or a mixture of B and the cubic (C) form which is stable at room temperature. This may be explained by suppression of the B to C transformation for Sm_2O_3, Eu_2O_3, Tb_2O_3 but the B-form is metastable at all temperatures for Y_2O_3, Er_2O_3 and Yb_2O_3 and its appearance in these oxides is thus related to the nucleation kinetics of B and C from the melt. 72988 Blue sputtered iridium oxide films (blue SIROFs). K.S.Kang, J.L.Shay (Bell Labs., Holmdel, NJ, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.766-9 (April 1983).
Reports on the preparation and properties of 'blue' sputtered iridium oxide films (blue SIROF) and compare their properties with those of previous 'black' SIROFs as well as anodically grown iridium oxide films (AIROFs). Blue SIROFs are prepared by reactive DC sputtering of iridium in argon/oxygen, 80/20 mixture, at deposition rates of about 200 Å/min onto substrates held at 238K. The physical properties of blue SIROF show characteristics similar to AIROFs. In contrast to SIROFs previously deposited in pure oxygen onto substrates held at 289K, the new films have an optical absorption spectrum which peaks at 610 nm. The cyclic voltammograms, the magnitude of the electronic conductivity change, and their density are closer to those of AIROFs than previous SIROFs. As electrochemical display electrodes, the blue SIROFs have an improved open-circuit bleached state and written-state memory, as well as an improved appearance. (22 refs.)

72989 Substrate heater and biasing electrode assembly for RF sputtering unit. C.A.Stone, A.Rozaj-Brvar, R.F.Davis (Materials Engng. Dept., North Carolina State Univ., Raleigh, NC, USA).
Rev. Sci. Instrum. (USA), vol.54, no.5, p.633-5 (May 1983).
Heating and biasing of a thin film during deposition is frequently desirable to improve the structural quality of the film and to remove entrapped gases and losely bound species on the surface. A large-diameter electrode assembly which allows both operations to occur simultaneously with a resulting variation of film thickness across a 2.54-cm wafer of ≤ 0.1 μm is described. (10 refs.)

72990 Design and operation of a high efficiency magnetron sputter coater. C.E.Nockolds, K.Moran, E.Dobson, A.Phillips (Electron Microscope Unit, Univ. of Sydney, Sydney, NSW, Australia).
Scanning Electron Microsc. (USA), pt.3, p.907-15 (1982).
A planar magnetron sputter coater has been developed for preparing specimens of examination in the SEM. The high ionizing efficiency of the coater is obtained by the use of an annular magnetic system which traps the high energy electrons in a ring close to the surface of the cathode. The increased interaction between the electrons and the gas atoms leads to fast coating rates, and allows a discharge to be maintained down to a vacuum level of approximately 0.05 Pa. The performance of the coater has been studied in terms of coating rate and heating rate as a function of vacuum. For Au coating at 0.1 Pa and a cathode to specimen distance of 50 mm the coating rate is 0.9 nm/sec and the temperature rise in the specimen is 0.15 K/sec. Au, Pt, Au/Pd and Ag films have been prepared at three different gas pressures (10, 1 and 0.1 Pa). The 10 Pa Au, Au/Pd and Pt films show severe cracking, but at 1 and 0.1 Pa, continuous films are formed. The Au/Pd and Pt films are finer grained than the Au and Ag films. The Au and Ag films become more coarse grained as the gas pressure is reduced. W and Ta films prepared at 0.1 Pa are very smooth and fine grained. (21 refs.)

72991 High rate sputtering technique using a hollow type target. H.Yamamoto, M.Tanaka (Coll. of Sci. & Technol., Nihon Univ., Funabashi, Japan).
Trans. Inst. Electron. & Commun. Eng. Jpn. Part C (Japan), vol.J66C, no.2, p.167-8 (Feb. 1983). In Japanese.
A new technique for a high rate sputtering deposition was demonstrated. Hollow type targets of Nb and W were sputtered. A sputtering power density up to about 25 W/cm^2 was attained at which an optimum deposition rate of about 1000 Å/min was observed for a tungsten target. (2 refs.)

81.15G Vacuum deposition

72992 Growth of single crystal epitaxial silicides on silicon by the use of template layers. R.T.Tung, J.M.Gibson, J.M.Poate (Bell Labs., Murray Hill, NJ, USA).
Appl. Phys. Lett. (USA), vol.42, no.10, p.888-90 (15 May 1983).
A novel crystal growth technique for silicide epitaxy is presented which utilizes thin silicide (>60 Å) template layers to pin the subsequent growth under ultrahigh vacuum conditions. Single crystal $NiSi_2$ films can be grown with either type A or type B orientations on Si(111). Continuous single crystal $NiSi_2$ is grown on Si(100) with a flat interface and uniform thickness. Thick $CoSi_2$ can be grown on Si(111) by a similar process using thicker templates. (10 refs.)

72993 How to place a Knudsen source to obtain optimal uniformity of film thickness on a spherical substrate holder. P.P.Elekes (Phys. Inst., Tech. Univ., Budapest, Hungary).
Vacuum (GB), vol.33, no.1-2, p.19-23 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Knudsen sources are placed in an offset position on the surface of the same sphere on which the substrates are located. Geometric positions for uniform film thicknesses are shown, i.e. favourable places for locating a thickness monitor. It is demonstrated that if the sphere rotates on its diameter parallel to the axis of symmetry of the Knudsen source with constant angular speed the film thickness at any point on the surface of the sphere (over the source) is identical after each complete turn. This leads to a simple relation between film thickness and quantity of material evaporated. Some considerations are given to the design of planetary systems. (3 refs.)

81.15H Chemical vapour deposition

72994 Thermodynamic optimisation in CVD processes involving candidate materials for photovoltaic solar energy conversion and for space applications. C.Bernard (Lab. de Thermodynamique et Phys.-Chimie Metall., Domaine Univ., St. Martin d'Heres, France).
High Temp.-High Pressures (GB), vol.14, no.4, p.377-81 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).
Three example applications of chemical vapour deposition (CVD) techniques that have recently become important in areas of current technological interest are given to show how detailed thermodynamic analysis of the deposition equilibria can be used to aid optimisation of the processes. The processes examined are: in-depth deposition of SiC in porous carbon-carbon materials; low-pressure GaAs vapour-phase epitaxy in the chloride system; and growth of AlSb on insulating substrates from organometallic gaseous species. (13 refs.)

72995 Influence of impurities on lateral polysilicon pn diodes. M.Dutoit (Centre Electronique Horloger SA, Neuchatel, Switzerland).
J. Electrochem. Soc. (USA), vol.130, no.4, p.967-8 (April 1983).
Shows that gaseous pollutants, which may inadvertently be present in the LPCVD reactor during deposition, can significantly alter the properties of polysilicon diodes. The impurities most likely to be found are H_2, O_2, and HCl. H_2 is a byproduct of the pyrolysis of SiH_4; O_2 may be introduced by leaks or be absorbed on the walls of the tube while the reactor is opened to room ambient, and HCl is used before each deposition to clear the wafers. (12 refs.)

72996 Silicon-germanium alloy growth control and characterization. L.I.Halberg, J.H.Nevin (Dept. of Electrical & Computer Engng., Univ. of Cincinnati, Cincinnati, OH, USA).
J. Electron. Mater. (USA), vol.11, no.4, p.779-93 (July 1982). [received: Nov. 1982]
Silicon-germanium alloy has been grown on silicon substrates by the hydrogen reduction of silicon tetrachloride and germanium tetrachloride as well as the pyrolysis of silane and germane. The film growth characteristics in the first few minutes have been studied using an SEM. Techniques have been developed for growing high germanium content films which are single crystal and have surface suitable for MOS device fabrication. (7 refs.)

72997 Study of the temperature field in a vertical cold wall reactor by holographic interferometry [CVD]. S.Benet, R.Berge, S.Brunet, S.Charar (Lab. de Phys. Appl. Univ. de Perpignan, Perpignan, France), B.Armas, C.Combescure.
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.2, p.77-88 (1982).
The study of the temperature field in a cold wall reactor was carried out using an interferometric method. The introduction of holographic techniques makes it possible to realise an interferometer presenting many advantages as compared to the classical Mach-Zehnder apparatus. The interferograms may be obtained either by the double exposure method or by that of the reference hologram allowing real time investigations, the latter being particularly interesting for time dependent phenomena. Quantitative processing is carried out on finite fringe interferograms so as to increase the measurement accuracy. (13 refs.)

72998 Recrystallization of amorphous and small grain size polycrystalline silicon. W.J.J.Schins, J.Bezemer, C.D.Ouwens, S.Radelaar.
Report EUR 8197 EN, Comm. European Communities, Luxembourg (1982), 43 pp. Contract 444-78-4 ESN.
Layers of polysilicon were grown by CVD on graphite. The positive influence of dopants (Al and B) on the high temperature recrystallisation and grain growth was investigated. A systematic study of recrystallisation of hot-deformed single and polycrystalline silicon was carried out. New grains are formed by nucleation and growth at temperatures between 1280 and 1410°C and the final grain size is a function of the degree of deformation. Experimental p-n junction solar cells on various substrates show that CVD grown cells on polycrystalline material are of good quality. A high concentration of Al in the substrates is not detrimental to the efficiency. Application of the proposed method on a large scale would require recrystallisation of thin layers (10-50 μm) of silicon on graphite. (9 refs.)

81.15J Ion plating and other vapour deposition

72999 Future prospects for application of ion deposition of thin films in microelectronics. V.P.Belevskii, I.V.Gusev.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.2, p.51-8 (1982). In Russian.
An analysis is made of the current state of the methods and conditions for producing thin films using numerous previously published articles and original results. Using as an example two high-precision processes (silicon autoepitaxy and the production of superconducting niobium films), a study is made of the interrelation of the parameters being monitored—the residual gas pressure, the condensation rate, the substrate pre-heating temperature, the ion energy and the correlation between the ionised and neutral components in the vapour flow onto the substrate. Diagrams illustrating these interrelations are given and it is shown that the bombardment of the film surface during growth with ions of the material being deposited causes a sharp reduction in the threshold of the sensitivity of the process to the residual gas pressure, substrate preheating temperature and other 'instrumental' factors which are hard to monitor. The ion deposition method is found to offer good prospects for the industrial production of thin layers with a perfect structure and acceptable electrophysical characteristics. (51 refs.) *L.M.H.*

73000 An optical emission study of the glow-discharge deposition of hydrogenated amorphous silicon from argon-silane mixtures. F.J.Kampas (Div. of Metall. & Materials Sci., Brookhaven Nat. Lab., Upton, NY, USA).
J. Appl. Phys. (USA), vol.54, no.5, p.2276-80 (May 1983).
Optical emission intensities from atomic silicon and argon and molecular hydrogen have been measured in silane-argon mixture glow discharges as a function of silane percentage and RF voltage. These measurements show that the electron concentration decreases and the average electron energy increases as the silane concentration increases. This dependence explains why the deposition rate of hydrogenated amorphous silicon from silane-noble gas mixtures is not proportional to the silane concentration. (23 refs.)

73001 Electron accelerated plasma for ion plating of refractory metal. J.Uramoto (Inst. of Plasma Phys., Nagoya Univ., Nagoyashi, Japan).
J. Vac. Soc. Jpn. (Japan), vol.26, no.1, p.15-21 (1983). In Japanese.
Discharge plasmas and electron beams for ion plating of refractory metals (especially, tungsten W) are researched. Two necessary conditions are required: a power concentration above 10 kW to hearth and a plasma production above a density of 10^{11}/cc around the center of the plasma or the beam. A high energy electron beam (>10 keV) with a space charge limit (~1A) can satisfy the power concentration, but the produced plasma density is too low because the ionization rate is very small. A low voltage discharge in a gas can produce a plasma source with a sufficient density, but the power concentration to hearth is not effective (only about 1/4 of total discharge power). Therefore, the large discharge current (>1000A) is required while the power loss and the discharge cathode emission become serious. To satisfy the two necessary conditions for ion plating of W, the authors propose to use an electron accelerated plasma in which the electrons are accelerated locally along a magnetic field, and have an energy of a few hundred electron volt and a current of several tens ampere. (17 refs.)

73002 Annealing effects in a-Si:H thin films prepared by glow discharge method. H.Kakinuma, S.Nishikawa, T.Iwabuchi, T.Watanabe, K.Kaminishi (Res. Lab., Oki Electric Industry Ltd., Tokyo, Japan).
J. Vac. Soc. Jpn. (Japan), vol.26, no.1, p.35-44 (1983). In Japanese.
Annealing effects on photoconductive, morphologic, and IR absorptional properties of glow discharge a-Si:H films are investigated. Samples are decomposited with pure silane changing two decomposition parameters, growth rate and substrate temperature (T_s). Photoconductivity (σ_p) of low T_s samples is extremely low but steeply increases by ~3 orders at certain T_s as T_s is raised, and the turning T_s depends on the growth rate. The σ_p of the low T_s samples increases by 1~2 orders with annealing up to ~250°C. This large change corresponds to the disappearance of the grain boundary observed by TEM. Dark conductivity (σ_d) at room temperature shows various transport mechanisms depending on the deposition conditions. Localized states density at E_f estimated from γ ($\sigma_p \propto F^{\gamma}$, F: intensity) decreases as T_s is raised or annealed up to 150~250°C. These results are discussed in some detail. (17 refs.)

73003 An investigation of microcrystalline films produced by a DC glow discharge in silane and hydrogen. D.E.Carlson, R.W.Smith (RCA Labs., Princeton, NJ, USA).
J. Electron. Mater. (USA), vol.11, no.4, p.749-60 (July 1982). [received: Nov. 1982]
Microcrystalline and amorphous Si:H films have been produced in a DC cathodic discharge in atmospheres containing silane dilute in hydrogen. The composition of the discharge atmosphere has a strong effect on the nucleation of microcrystalline Si:H films. Dopants such as boron enhance the formation of microcrystals while higher silanes such as disilane inhibit crystallization. The presence of other gases in the discharge atmosphere generally inhibits the formation of microcrystals. (12 refs.)

81.15L Deposition from liquid phases (melts and solutions)

73004 The growth of Cu_2S on polished or etched single crystal CdS substrates [for photovoltaic cells]. G.J.Russell, S.Oktik, J.Woods (Dept. of Appl. Phys. & Electronics, Univ. of Durham, Durham, England).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.229-32 (May 1983).
The authors report a study of the growth rates of Cu_2S on planes of both etched and mechanically polished surfaces of single crystal CdS. By using a SEM, it has been possible to extend the measurement to thinner layers which are comparable with those actually used in the preparation of photovoltaic cells. (18 refs.)

73005 Electrochemical nucleation and growth of silicon in molten fluorides. K.L.Carleton, J.M.Olson, A.Kibbler (Solar Energy Res. Inst., Golden, CO, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.782-6 (April 1983).
The electrochemical nucleation and growth of silicon on vitreous carbon and graphite are characterized. The anode is a copper:silicon alloy and the electrolyte is a molten solution of $KF:LiF:K_2SiF_6$ at 750°C. SEM examination of the initial stages of electrodeposition shows that the nucleation process is instantaneous and is followed by three dimensional growth. Because the nucleation is instantaneous, the initial nucleation density and the grain size of the deposited silicon can be controlled. Existing theoretical models for nucleation and their failure to model this system are also discussed. (14 refs.)

73006 A study on electroless plating of cobalt alloy films for perpendicular recording. T.Osaka, N.Kasai, I.Koiwa (Dept. of Appl. Chem., Waseda Univ., Okubo, Shinjuku-ku, Tokyo, Japan), F.Goto.
J. Electrochem. Soc. (USA), vol.130, no.4, p.790-4 (April 1983).
An electroless plating bath for the preparation of perpendicular recording media was developed. It was found that the HCP structure of Co-P is oriented normal to the film plane with the Mn codeposition into the films. First, an ammoniacal malonate-malate bath, containing $MnSO_4$ was selected. Nickel was codeposited into the films in order to decrease the saturation magnetization, *Ms* since low *Ms* is necessary to decrease the demagnetizing field. Second, effects were investigated for three factors (i.e. $MnSO_4$ concentration, bath *p*H and $NiSO_4$ concentration) causing the c-axis perpendicular orientation of the film properties. Optimum plating conditions for perpendicular recording media were thus determined. (17 refs.)

73007 The effect of some additives on electroless copper deposition. M.Paunovic, R.Arndt (PCK Technol. Div., Kollmorgen Corp., Melville, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.794-9 (April 1983).
The effect of adenine, guanine, saccharin, and coumarin on electroless copper deposition has been studied by cyclic voltammetry and the weight gain method. It was found that guanine and adenine accelerate electroless copper deposition. Coumarin and Saccharin have almost no effect on the deposition process. Differences in the effect of these two groups of additives have been correlated to differences in the electronic structure of molecules. (31 refs.)

73008 Electrodeposition of conducting transition metal oxide/hydroxide films from aqueous solution. D.Tench, L.F.Warren (Microelectronics Res. & Dev. Center, Rockwell Internat., Thousand Oaks, CA, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.869-72 (April 1983).
Reports results describing a general technique for the electrochemical deposition of oxide/hydroxide films of copper, nickel, cobalt, iron, and manganese from aqueous solution. The general properties of these materials, some of which are new, are also discussed. (11 refs.)

73009 Tin(IV)-based photoselective metal deposition of cobalt and nickel from alkaline baths. I.Kiflawi (Precision Electronic Components Ltd., Toronto, Ontario, Canada), M.Schlesinger.
J. Electrochem. Soc. (USA), vol.130, no.4, p.872-4 (April 1983).
First the authors report that the production of a negative photoimage using alkaline nickel or cobalt metallizing baths is possible. Then they attempt to further clarify possible mechanisms for the influence of ultraviolet irradiation on subsequent metal deposition. (7 refs.)

73010 The effect of pH on electroless copper deposition. J.Duffy, L.Pearson, M.Paunovic (PCK Technol. Div., Kollmorgen Corp., Melville, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.876-80 (April 1983).
Electroless copper deposition is affected by pH. In order to formulate theory of the rate vs. pH function, the authors have selected two approaches: electrochemical and spectroscopic. In the electrochemical approach, they have investigated the effect of pH on the rest potentials and the transfer coefficients for partial processes composing electroless copper deposition. In the spectroscopic approach they have investigated the effects of pH on the composition of the adsorption film on the substrate. The importance of these studies is twofold: to elucidate the dependence of the rate of electroless copper deposition on *p*H and to interpret the dependence of the effect of additives on pH (13-16). The accelerating effect of an additive is usually observed in the range of the peak in the rate vs. pH function. The inhibiting effect of the same additive is observed at the lower and the higher pH values. For these reasons, Auger spectra have been taken for three characteristic values around the maximum. (32 refs.)

73011 Optimum conditions for baking of indium. M.Janson (Inst. of Microwave Technol., Stockholm, Sweden).
J. Electrochem. Soc. (USA), vol.130, no.4, p.960-2 (April 1983).
Calculations of SiO partial pressure over an indium melt with dissolved silicon in a moist hydrogen atmosphere are reported. The results are given as a function of temperature, water vapor pressure, and concentration of silicon in the melt, both with and without SiO_2 present. The influence of the total pressure in the baking system is considered, and the calculations indicate that by using a pressure lower than atmospheric, the efficiency of the baking should be significantly increased. The time constant of the baking process is, furthermore, shown to be critically dependent on water vapor partial pressure. These results should be valuable when one wants to find the optimum baking procedure to remove residual silicon from indium. (9 refs.)

73012 The colour of gold and gold alloy electrodeposits. D.J.Arrowsmith (Dept. of Metall. & Materials Engng., Univ. of Aston, Birmingham, England), G.Brown.
Trans. Inst. Met. Finish. (GB), vol.61, pt.1, p.1-8 (Spring 1983).
The thickness of gold required to cover the colour of the substrate has been determined and found to be 0.23 μm for a matt gold deposit on a substrate prepared to 600 grit and 0.06 μm for a bright gold deposit on a surface prepared to a 6 μm diamond finish. A general method of defining covering power is proposed. The change in colour from additions of copper and silver to a gold bath was monitored by a spectrophotometric technique. As the silver content of the bath was increased there was a smooth transition of colour from yellow through green to white; the smoothness of the transition is ascribed to the structural homogeneity of the gold-silver system. The addition of copper gives an undulating effect on the colour change which is thought to be due to the presence of long range order in the gold-copper system exemplified by the formation of superlattices based on CuAu and Cu_3Au. (6 refs.)

73013 A new high performance sodium chloride acid zinc plating process. R.J.Lash (Udylite/Sel-Rex, Warren, MI, USA).
Trans. Inst. Met. Finish. (GB), vol.61, pt.1, p.25-9 (Spring 1983).
An acid zinc plating process which uses a sodium chloride supporting electrolyte is now practical. Cathodic depolarisation caused by the smaller sodium ion in the electric double layer can have a detrimental effect on the performance of conventional potassium chloride acid zinc brighteners. This problem is overcome with the use of special brighteners which are apparently stronger cathode inhibitors. (19 refs.)

73014 Electrodeposition of silver alloy powders on rotating and vibrating cathodes. A.T.Kuhn (Inst. of Dental Surgery, Eastman Dental Hospital, London, England), P.Neufeld, D.W.Cruickshanks-Boyd.
Trans. Inst. Met. Finish. (GB), vol.61, pt.1, p.30-4 (Spring 1983).
A detailed study of the manufacture of Ag-Sn and Ag-Sn-Cu powder deposits at rotating cylinder and vibrating cathodes is reported. The electrolyte used was a cyanide-stannate bath. The effects of cathode potential, mass transport (rotation rate of cylinder) and temperature were examined, as well as use of K^+ in place of Na^+ cations. It is shown that the silver deposition process is mass transport controlled, the tin activation controlled. There is no evidence to suggest that the various components of the bath interact with one another. The full range of Ag-Sn compositions can be formed as powders, and it appears that Cu in any proportion can be included in these powders. Powders having the composition of commercially available dental amalgam alloys (Ag-28% Sn, O-30% Cu) were prepared. (19 refs.)

73015 Some mechanical and electrochemical properties of electroless nickel. A.J.Gould.
Univ. Nottingham, England thesis, 1982
Experiments have demonstrated that the temperature and pH of the plating bath had a significant effect upon the deposit's composition as well as the mixed electrode potential of the plating process. Maintaining a constant potential, close to that of the mixed electrode potential, with a potentiostat, significantly reduced the increase in phosphorous content (0.8 wt.% P compared to 2.1 wt.% P) experienced during plating. The cathodic polarisation of the plating system improved the plating rate whilst not affecting the composition. Therefore the additional electrolyte processes, despite being two electron processes, co-deposited nickel and phosphorous. The electroless nickel deposit, plated by the potentiostatic technique, improved the fretting wear resistance of the EN25 substrate provided that it was at least 25 μm thick. Heat treatment of the coating in the range 200-400°C improved the wear resistance for all coating thicknesses tested. Raising the temperature of the fretting tests to 350°C increased the wear rate but at 600°C a protective oxide film or glaze was formed which provided good wear resistance. Serious reductions in the fatigue strength of the EN25 were produced by the coating in the as-deposited (20%) and heat treated at 400°C to maximum hardness (45%) conditions. The conjoint action of fretting and fatigue further reduced the fatigue strength by 53% and 70% respectively.

73016 Depot de couches polycristallines de silicium sur un substrat conducteur a partir de la phase liquide (Deposition of polycrystalline Si films on conducting substrates from the liquid phase). C.Belouet.
Report EUR 8305 FR, Comm. European Communities, Luxembourg (1983), 84 pp. In French. Contract 749-78-7/ESF.
Reports on the results of a one-year study of the growth of polysilicon layers on a carbon substrate by the RAD (ribbon against drop) process. The new pulling equipment, the characteristics of the ribbon substrates and the morphological and electrical properties of the layers are successively described. Deposition lengths up to 80 cm have been achieved at pulling rates 2 to 6 cm/mn on typical substrates (Papyex coated by pyrocarbon deposited at 2000°C). Elastic and thermal properties of the ribbon substrates have been investigated and a preliminary study of the strains in the multilayer Si-substrate is presented. The anisotropy of the reactivity of pyrocarbon with molten silicon is evidenced. Finally, the feasibility of Si-substrates ohmic contacts is demonstrated. On the basis of all the results accumulated, it is concluded that AM1 conversion efficiencies of 10% can be achieved for n^+/p homojunction cells.

81.20 OTHER METHODS OF PREPARATION OF MATERIALS

81.20E Powder techniques, compaction and sintering

73017 Sintering of porous glass. T.H.Elmer (Corning Glass Works, Corning, NY, USA).
Am. Ceram. Soc. Bull. (USA), vol.62, no.4, p.513-16 (April 1983).
The sintering of porous glass was monitored by measuring changes in length, surface area, pore size, weight loss, and moisture adsorption capacity of porous specimens after various stages of heating. Shrinkage was minimal up to ≈800°C. But above 900°C, where viscous flow becomes significant, the sintering rate increased dramatically. Reactions involving boron, water, and siloxane bridges are postulated during the consolidation of the porous structure into an impervious, clear glass. (25 refs.)

73018 Macromechanism of powder deformation in the incoherent zone during rolling. O.A.Katrus (Inst. of Materials Sci., Acad. of Sci., Ukrainian SSR).

Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.683-8 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.1-7 (Sept. 1982). [received: March 1983]

It is concluded that observation of the deformation of a free-flowing material through transparent hopper walls is a technique yielding a great deal of useful information and enabling the deformation behavior of powders to be studied in the lag zone (breaks in the velocity field, formation of arch structures, and the like). A binding link between the geometric and physical parameters of the powder rolling process is the initial powder compressibility. An increase in the intensity of the shear deformation of powders before the commencement of their irreversible densification suggests that impeded deformation zones may not be able to form above the angle of rolling. (12 refs.)

73019 Kinematics of powder being rolled in the lag zone. E.B.Lozhechnikov, V.V.Lozhechnik, O.V.Chachin, A.I.Shilovich (Polytech. Inst., Minsk, Belorussian SSR).

Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.688-91 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.8-11 (Sept. 1982). [received: March 1983]

It was found that the rate of travel of powder in plane sections decreased with increasing distance from the roll surfaces. In the vicinity of the plane of symmetry, at $X=0$, powder may be forced to move in the direction opposite to the rolling direction. Feed of powder into this zone is effected through its movement in the direction at right angles to the rolling direction. (3 refs.)

73020 Control over the structure of hard metals and other heterophase materials produced by liquid-phase sintering. I. Liquid-phase migration and general principles of sintering of 'skeletonless' alloys. O.P.Kolchin (All-Union Sci.-Res. & Design Inst. of Refractory Metals & Hard Alloys, USSR).

Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.694-7 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.14-18 (Sept. 1982). [received: March 1983]

It is concluded that binder migration can be prevented or at least minimised by ensuring even heating of the whole blank on transition to LPS and during the melting of the binder, and even cooling after LPS and during the solidification of the melt. This can best be achieved in stationary, preferably vacuum, furnaces. Excessive heating of blanks above the melting point of their binder and prolonged soaking during LPS must be avoided. (12 refs.)

73021 Hot pressing dilatometry in the study of sintering mechanisms. R.J.Brook, E.Gilbart, D.Hind, J.Vieira (Dept. of Ceramics, Univ. of Leeds, Leeds, England).

Sintering - Theory and Practice. Proceedings of the 5th International Round Table Conference on Sintering, Portoroz, Yugoslavia, 7-10 Sept. 1981 (Amsterdam, Netherlands: Elsevier 1982), p.585-90

The use of pressure as a variable during studies of sintering is valuable in two ways; it indirectly reduces the interference from such processes as grain growth and surface diffusion and it directly distinguishes between mechanisms with different pressure dependence. Results for the sintering of β alumina and magnesia are reported. (8 refs.)

73022 Recent trends in understanding dynamic compaction of powders. H.Palmour,III (North Carolina State Univ., Raleigh, NC, USA), V.D.Linse, R.M.Spriggs.

Sintering - Theory and Practice. Proceedings of the 5th International Round Table Conference on Sintering, Portoroz, Yugoslavia, 7-10 Sept. 1981 (Amsterdam, Netherlands: Elsevier 1982), p.611-18

Reviews discernible trends toward improved scientific understanding of the behaviour of particulate materials being subjected to compaction by shock waves. (29 refs.)

73023 The modeling of rapidly solidified powders. R.J.Patterson,II (Government Products Div., Pratt & Whitney Aircraft Group, West Palm Beach, FL, USA).

Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.123-30

In the past several years rapid solidification technology has been extended from the realm of splats and foils to powders. This paper surveys several of the models that have been developed for such powders and considers their comparison with experimental results. (26 refs.)

73024 An automated laboratory apparatus for the production of rapidly solidified submicron powders. J.Perel, J.F.Mahoney, S.Taylor, Z.Shanfield, C.Levi (Phrasor Sci. Inc., Duarte, CA, USA).

Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.131-6

The electrohydrodynamic (EHD) method of spraying fine liquid droplets from a liquid state, in a vacuum environment, was developed and used to produce amorphous, microcrystalline, single crystal, bicrystalline and tricrystalline powders. Studies of these powders have contributed towards increasing the knowledge of extended solubility, nucleation, metastable phases, undercooling effects, etc. Coatings and films have been produced by collecting the liquid droplets before solidification. An automated instrument based upon the EHD method, the micro-particle processor, is computer operated and allow a material scientist not completely acquainted with the EHD process to perform sophisticated experiments on materials of his choosing. Electron transparent powders close to 3 μm and large powders up to 10 μm have been collected and observed. Cooling rates above 10^7 K/s have been achieved. Applications using powders include: new alloy compositions, use as AEM standards, in-situ remelt experiments in the electron microscope etc. (4 refs.)

73025 Analysis of in situ rapid solidification of submicron Al-Ge eutectic powders using transmission electron microscopy. M.J.Kaufman, H.L.Fraser (Materials Res. Lab., Univ. of Illinois, Urbana, IL, USA).

Metall. Trans. A (USA), vol.14A, no.4, p.623-33 (April 1983).

Submicron powders of Al-30.3 at. pct Ge (eutectic), produced by electrohydrodynamic atomization, have been analyzed in a transmission electron microscope operating at 120 kV. Amorphous and complex crystalline structures were observed in the as-atomized condition. By using the electron beam as a local heating source, powders could be either annealed at temperatures below their melting point or melted. Molten powders were quenched at various cooling rates by altering the rate of beam obstruction. Using this technique, nonequilibrium structures were produced including metastable phases and mixed amorphous/crystalline microstructures. These various structures have been related to cooling rates and compared with the as-atomized structures. Crystallization of the amorphous regions produced by this technique has also been studied. (16 refs.)

73026 Metallic glasses. P.G.Zielinski (Inst. Inzynierii Materialowej, Politech. Warszawska, Warszawska, Poland).

Szklo & Ceram. (Poland), vol.33, no.3-4, p.61-5 (Sept.-Dec. 1982). In Polish. [received: April 1983]

Glass transformations in metallic systems are described. The technique of rapid cooling from the liquid phase for the production of metallic glasses is discussed. The method of continuous casting of metallic glasses in the form of ribbons is analysed. The conditions for securing the glass transformation and of obtaining a commercial product are described. (22 refs.)

73027 Effect of composition of powder mixtures and rolling temperature on the compactibility and properties of strip. G.A.Vinogradov, A.M.Musikhin, A.I.Otrok (Inst. of Materials Sci., Acad. of Sci., Ukrainian SSR).

Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.691-3 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.11-13 (Sept. 1982). [received: March 1983]

Results are presented of a study of the rolling of high-alloy mixtures of PZh4r atomized iron powder (GOST 9849-74) and ground FS75 ferrosilicon (GOST 1415-70). The effect of mixture composition on the mechanical properties of cold- and hot-rolled strip was determined. (4 refs.)

73028 Electric-spark alloying (ESA) of steel with titanium carbide in its homogeneity range. A.D.Verkhoturov, F.F.Egorov, M.D.Smolin, I.A.Podchernyaeva (Inst. of Materials Sci., Acad. of Sci., Ukrainian SSR).

Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.705-8 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.28-31 (Sept. 1982). [received: March 1983]

It is concluded that correlation exists between changes in the parameters of the process of ESA of steel with titanium carbide in its homogeneity range and changes in the electronic structure of TiC_x. The erosion of titanium carbide, weight gain of the steel cathode, and proportion of fine-fraction particles in the erosion products of TiC grow with increasing degree of completeness of the carbon sublattice. This promotes growth of the alloyed layer, and is a result of a strengthening of the covalent component of the Ti-C bond, which predominates in the electronic energy spectrum of TiC_x. It has been found that the number of pearlitic colonies in the spark-heat-affected zone falls with decreasing distance from the alloyed surface, due to carbon impoverishment of this zone resulting from the carbon combining chemically with the titanium. (6 refs.)

73029 Isostatic shaping of parts in a heat-resisting nickel alloy. V.K.Orlov, M.A.Mukhametkulov, E.P.Kratt, V.I.Kosin, V.I.Kostyukov (All-Union Inst. of Light Alloys, USSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.747-9 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.75-8 (Sept. 1982). [received: March 1983]
A study was made of the variation of the density and thermal diffusivity of EP-741P nickel superalloy powders during isostatic shaping in hermetically sealed capsules. The steel capsules used in experiments had diameters of 90, 350, and 505 mm and heights of 300, 142, and 180 mm, respectively. The capsules were fitted with thermocouples. Special hermetic devices were employed for passing the thermocouples through the capsule walls. The thermocouple junctions were made hermetic by welding the thermoelectrodes together with the cable armor. Capsules filled with 70- to 300-μm-diameter granules were subjected to vibratory densification, after which they were degassed, hermetically sealed, and heated in an isostatic press under the required conditions. Temperature measurements were made with a PP-63 potentiometer. (4 refs.)

73030 Reductive additives in powder metallurgically prepared Cu-Nb_3Sn composite wires. K.Mrowiec, R.Bormann, H.C.Freyhardt (Inst. fur Metallphys., Univ. Gottingen und Sonderforschungsbereich Gottingen/Clausthal, Germany).
Z. Metallkd. (Germany), vol.74, no.5, p.323-9 (May 1983). In German.
The critical currents of microcomposite superconductors strongly depend on a well-developed fibre structure. Oxygen, incorporated during the powder metallurgical process, complicates the preparation of Cu-Nb_3Sn microcomposite wires. By adding a powder component with a larger binding enthalpy for oxygen than Nb, the oxygen can be bound as the appropriate oxide. The development of the fibre structure during cold deformation of the compound is influenced by the solubility of the reductive additives Al, Mg, Zr, Hf and Ca in the copper matrix as well as by the distribution of the copper-rich phases and oxide particles. By measuring the critical temperature of Nb, the residual oxygen content can be estimated which characterizes the degree of purification. (23 refs.)

73031 Formation of properties of powdered carbide steels under quasi-isostatic pressing. V.M.Gorokhov, M.M.Dechko, E.A.Doroshkevich, O.V.Roman (Powder Metall. Assoc., Minsk, USSR).
Sintering - Theory and Practice. Proceedings of the 5th International Round Table Conference on Sintering, Portoroz, Yugoslavia, 7-10 Sept. 1981 (Amsterdam, Netherlands: Elsevier 1982), p.625-9
The method of quasiisostatic hot pressing with the pressure applied on a compacting part through intervening media provides for high efficiency densification of porous materials during compaction. High pressure compaction and shear deformations in material make it possible to produce high density parts with fine structure and improved physical and mechanical properties. This method is believed to produce best results when applied to high density billets production from poorly compactable materials including hard alloys and carbide steels. (4 refs.)

73032 Nickel base metallic glass powders for application as plasma sprayed coatings. V.Panchanathan (Marko Materials Inc., N Billerica, MA, USA), C.L.Tsai, S.Whang.
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.137-9
New nickel rich alloys containing molybdenum and chromium prepared as metallic powders are reported. Using standard plasma spray techniques, these powders (-170 mesh) can be deposited onto metallic substrates as dense, well bonded structural strength, hardness and good corrosion resistance in various corrosive media. (2 refs.)

73033 Cooling rates and fine microstructures of RSR and argon atomized superalloy powders. F.Cosandey, R.D.Kissinger, J.K.Tien (Henry Krumb School of Mines, Columbia Univ., New York, NY, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.173-8
Superalloy powders of an IN 792 plus Hf type alloy produced from rapid solidification rate (RSR) and argon atomized process (AA) techniques are analyzed and compared according to particle size. Characterization of powders include surface and interior morphology, particle size and void distribution, cooling microstructures, microcrystallinity, microsegregation and especially dendrite arm spacing and cooling rates. It is found that, for the alloy studied, RSR cooling rates are a factor of only two to four greater than those for AA, regardless of particle size. (9 refs.)

81.20J Dispersion-,fibre-, and platelet-reinforced metal-based composites

73034 Production, properties, and possible application of dispersion hardened copper. H.Oppenheim (Inst. fur Chem. Technol Anorganischer Stoffe, Tech. Univ. Wien, Wien, Austria).
Z. Metallkd. (Germany), vol.74, no.5, p.319-22 (May 1983). In German.
Dispersion hardened copper with a content of Al_2O_3 up to 24 vol.% can be produced by milling of Cu- and Al-powder in oxidizing atmosphere, subsequent diffusion and reduction annealing of the milled powder and compaction by hot extrusion or powder forging. The properties of the metals are determined both by the content of dispersoid and the production parameters. Careful choice and control of the temperature is of great importance for powder forging, for the strength will be reduced at too high temperatures by recovery and recrystallization and at too low temperatures by unsound bounding between the individual granules. The materials seem to be interesting for applications where high strength and good electrical conductivity at high temperatures are requested. Experiments where these mateials were used as electrode tips for point welding gave good results. (24 refs.)

73035 Casting of laminated ribbon using a modified melt-spinning technique. R.V.Raman (Battelle Columbus Labs., Columbus, OH, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.141-4
Laminated metal-metal and metal-semiconductor ribbons have been prepared by a modified melt-spinning technique. Characterization studies have been carried out on laminated Sn-Zn, Ge-Al, InSb-CuZr and some other materials. Characteristics of these ribbons and their potential applications are described. (11 refs.)

73036 Consolidation of $Ni_{60}Nb_{40}$ metallic glass strips into metal matrix composites. S.J.Cytron (US Army Armament Res. & Dev. Command, Dover, NJ, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.145-9
To fully utilize the promising mechanical properties of metallic glasses, consolidation techniques need to be developed to incorporate them into large bulk forms. The author describes preliminary results on the consolidation of $Ni_{60}Nb_{40}$ metallic glass strips into an aluminum alloy matrix. The consolidation was achieved without the degradation of the metallic glass by employing a superplastic aluminum alloy as the matrix material. The consolidations were accomplished at a superplastic forming temperature compatible with the metal matrix material and sufficiently below the critical 650°C crystallization temperature of the $Ni_{60}Nb_{40}$ metallic glass. Initial studies employed an aluminum$-$5% calcium$-$5% zinc alloy as the metal matrix material. (11 refs.)

81.20L Ceramics and refractories

73037 Dependence of compaction on the glass transition temperature of the binder phase. R.A.DiMilia, J.S.Reed (Alfred Univ., Alfred, NY, USA).
Am. Ceram. Soc. Bull. (USA), vol.62, no.4, p.484-8 (April 1983).
Spray-dried alumina powder granules were compacted at 24°C in a polished, hardened steel die using a constant punch velocity. Variables investigated were the concentration of polyvinyl alcohol binder phase (1-2.7 wt.%), concentration of absorbed moisture (0.2-1.6 wt.%), and the basic particle size. The yield strength of powder granules decreased markedly when the concentration of adsorbed moisture was sufficient to lower the glass transition temperature (T_g) of the binder below 24°C. The yield strength ranged less widely with binder content when the granules were stored at higher humidity. Power particle size affected both the granule strength and the maximum pressed density. Three distinct compaction stages were characterized. Hg porosimetry and microstructure analyses indicated that the reduction of intergranule porosity as dependent on granules strength and a denser, more uniform compact is produced when T_g of the binder phase is below the pressing temperature. (7 refs.)

73038 Densification, thermal diffusion and Na vapor resistance of Y_2O_3 ceramics. Y.Tsukuda (Hitachi Metals Ltd., Saitama, Japan).
Am. Ceram. Soc. Bull. (USA), vol.62, no.4, p.510-12 (April 1983).
The sintering rate resistivity against corrosion by saturated Na vapour, and thermal diffusivity of black (reduced) sintered Y_2O_3 bodies were studied and compared with those for colorless Y_2O_3 bodies. The sintering rate for black Y_2O_3 bodies at 2373 to 2537K is higher than that for colorless bodies. Both types of bodies exhibit the same resistivity to corrosion by saturated Na vapour at 1473K. The thermal diffusivity and conductivity of black Y_2O_3 bodies are greater than those of colorless bodies. (9 refs.)

73039 Hot-pressed silicon nitride with a small amount of MgO added. S.B.Hanna (Refractories Lab., Nat. Res. Centre, Cairo, Egypt), G.Grathwohl, F.Thummler.
CFI-Ceram. Forum Int. Ber. Dtsch. Keram. Ges. (Germany), vol.60, no.2-3, p.64-9 (April 1983). In German, English.
Hot-pressed Si_3N_4 (HPSN) was mixed with a small amount of MgO ($\leq$0.8%). The shrinkage undergone during hot-pressing and the ultimate density were studied as functions of manufacturing conditions. The phase transition and formation of microstructure during hot-pressing were monitored and described. HPSN specimens containing 0.07% MgO can be compacted to 99% TD. In all of the examined specimens, the entire α-Si_3N_4 content was converted to β-Si_3N_4. Increasing the MgO content was found to favor the appearance of elongated β grains, whereby the average grain size increased from 0.8 to 1.7 microns. (7 refs.)

73040 On the use of powder beds in the nitridation and subsequent densification of RBSN. J.R.G.Evans, A.J.Moulson (Dept. of Ceramics, Univ. of Leeds, Leeds, England).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.236-8 (May 1983).
The authors show that unless the MgO content of RBSN is controlled at all stages in the fabrication process, reproducible sintering kinetics cannot be obtained nor optimum densities achieved. The use of powder beds both during nitridation and densification is shown to be one way of reducing MgO loss. (4 refs.)

73041 Formation of NbC and TaC by solid-state reaction. S.Shimada, T.Koyama, K.Kodaira, T.Mastushita (Dept. of Appl. Chem., Hokkaido Univ., Sapporo, Japan).
J. Mater. Sci. (GB), vol.18, no.5, p.1291-6 (May 1983).
The formation of NbC and TaC by solid-state reaction of Nb_2O_5 and Ta_2O_5 with carbon, respectively, was studied at 1000 to 1285°C by X-ray diffraction. Factors affecting the formation of the carbides, such as the nature of the

reaction vessel, the molar ratio of carbon/oxide, the form of reactant carbon, etc., were examined. By covering the graphite crucible and increasing the molar ratio of carbon to oxide. Complete formation of NbC and TaC could be achieved in about 60 min at low temperatures (1170 and 1225°C, respectively). The beneficial effect of covering the crucible is ascribed to the retention of CO which facilitates the reaction at low temperatures. The formation kinetics of NbC and TaC obey a first-order equation, with activation energies of 90 and 93 kcal mol^{-1}, respectively. Possible mechanisms for the solid-state reactions are discussed. (7 refs.)

73042 Sintering of PZT ceramics. II. Effect of PbO content on densification kinetics. A.I.Kingon, J.B.Clark (Nat. Phys. Res. Lab., CSIR, Pretoria, S Africa).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.256-60 (April 1983).
For pt.I see ibid., vol.66, no.4, p.253-6 (1983). The presence of a PbO-rich liquid phase was previously shown to affect the densification of lead zirconate-lead titanate (PZT) ceramics. The authors attempt to quantify the role of this liquid phase. Increasing amounts of PbO-rich liquid phase is shown to increase the rates of densification in the initial and intermediate stages, but lower the final density. This behavior is discussed. In the case of PbO-deficient samples, the amount of the deficiency is shown to affect the densification rate at the final stage. (14 refs.)

73043 Investigation of phase stability in the system SiC-AlN. W.Rafaniello, M.R.Plichta, A.V.Virkar (Dept. of Materials Sci. & Engng., Univ. of Utah, Salt Lake City, UT, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.272-6 (April 1983).
Dense samples of several compositions in the system SiC-AlN were fabricated by hot-pressing. The SiC-AlN powder was prepared by carbothermal reduction of an intimate mixture of alumina, silica, and carbon in a nitrogen atmosphere. X-ray diffraction and electron and optical microscopy were used to determine the chemical and microstructural characteristics of the hot-pressed specimens. Materials with bulk compositions between 15 and 75 wt.% AlN were found to be nonhomogeneous when hot-pressed below 2100°C. These materials were determined to be a mixture of SiC-AlN solid solutions with different compositions. The observed compositional variations were distinctly bimodal. The source of the inhomogeneity was the starting SiC-AlN powder. (9 refs.)

73044 Specific volume diagrams for ceramic processing. G.Y.Onoda,Jr. (Univ. of Florida, Gainesville, FL, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.297-301 (April 1983).
Graphical procedures are presented for analyzing the volume-weight relations in ceramic particulate systems encountered in processing. The procedures emphasize the advantages of working with specific volume rather than density. By using the concept of partial specific volumes, the expected variations in specific volume with composition for many special cases are readily deduced. Comparing experimental and theoretical variations gives meaningful insights into the space-filling characteristics of real systems. (5 refs.)

73045 Sintering magnesium oxide obtained by the chemical beneficiation of magnesite. K.V.Simonov, L.D.Bocharov, N.S.Afinogenova, V.G.Abbakumov, V.M.Gropyanov (Leningrad Technol. Inst. for Cellulose-Paper Industry, USSR).
Refractories (USA), vol.23, no.7-8, p.375-83 (July-Aug. 1982). Translation of: *Ogneupory (USSR),* vol.23, no.7, p.43-50 (July 1982). [received: April 1983]
A quantitative relationship was established for sintering chemically beneficiated magnesite and a method of obtaining the MgO; also established were the parameters of hydrolysis of the magnesium chloride, the quantity of residual volatiles, the temperature and rate of thermal activation of residual volatiles, the temperature and rate of thermal activation of the magnesium oxide, not washed, and washed to get rid of the calcium impurities, and also the completeness of the hydration of the magnesium oxide during leaching. A production flow line is proposed for obtaining from the enriched material sintered periclase clinkers differing in density and degree of purity. (7 refs.)

73046 Isostatic pressing technology for refractory materials. E.V.Degtyareva, Ya.M.Grinberg (Kharkov Automobile-Road Komsomol Inst., Ukrainian SSR).
Refractories (USA), vol.23, no.7-8, p.395-401 (July-Aug. 1982). Translation of: *Ogneupory (USSR),* vol.23, no.8, p.6-13 (Aug. 1982). [received: April 1983]
In the USSR and abroad numerous investigations have been carried out into the process of isostatic pressing of refractories and ceramics. The method is distinguished primarily by excellent physical properties, and density and strength which are uniform throughout the volume. The method is useful for making large, complex articles, including those which cannot be shaped by other methods. Isostatic pressing is widely used in various technologies. At present, Soviet and foreign industries have shown that it is advantageous to develop this method for the metallurgical industry, in particular for producing stopper-monoblocks and nozzles for the donkey ladles of continuous casting machines, crucibles, etc. (44 refs.)

73047 Dependence of the dielectric properties, porosity, and apparent density of quartz ceramic on the phase of composition. Yu.A.Polonskii, V.G.Sloushch, T.I.Litovskaya, S.P.Shmitt-Fogelevich (Eastern Inst. of Refractories, USSR).
Refractories (USA), vol.23, no.7-8, p.432-6 (July-Aug. 1982). Translation of: *Ogneupory (USSR),* vol.23, no.8, p.44-8 (Aug. 1982). [received: April 1983]
It has been established that there is a connection between the porosity, the apparent density, and the concentration of cristobalite and the dielectric constant of a quartz ceramic; this connection may be used to carry out online, nondestructive monitoring of quality. A reduction in porosity of the quartz ceramic associated with an increase in temperature is accompanied by an increase in the concentration of cristobalite. In the experimental quartz ceramic a significant amount of cristobalite (>5%) appeared with a porosity <13%. (10 refs.)

73048 Some properties of fine-grained mixtures of $ZrSiO_4$-ZrO_2. I.G.Orlova, A.I.Gudilina, N.V.Gul'ko (Sci.-Res. Inst. of Refractories, Ukrainian SSR).
Refractories (USA), vol.23, no.7-8, p.437-41 (July-Aug. 1982). Translation of: *Ogneupory (USSR),* vol.23, no.8, p.48-53 (Aug. 1982). [received: April 1983]
The effect of additions of ZrO_2 in monoclinic and cubic modifications and also of $Zr(OH)_4$ on the swelling, thermal-shock resistance, and glass-resistance of high-density, zircon refractories has been studied. It is shown that the most effective addition for lowering the additional growth of the refractory almost fivefold was a mixture consisting of 9.5% monoclinic ZrO_2 and 0.5% $Zr(OH)_4$. This additive also significantly increased the thermal-shock resistance of the zircon refractories and the glass resistance as a result of the lower decomposition of $ZrSiO_4$ and the higher concentration of ZrO_2 in the contact zone. The density and electrical resistivity of the refractory was maintained at a high level. (7 refs.)

73049 Effect of sintering conditions on the microstructure and electromagnetic properties of Li-Mg-Mn ferrite memory elements. V.M.Minin.
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.698-701 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR),* vol.21, no.9, p.19-23 (Sept. 1982). [received: March 1983]
A study was made of the effect of sintering conditions on the microstructure and electromagnetic properties of memory elements from a thermally stable Li-Mg-Mn ferrite produced from a charge of composition corresponding to 3 VT grade. Shrinkage measurements were made on 35-mm-diameter, 40-mm-high specimens whose density before sintering was 2.2 ± 0.3 g/cm^3. The ferrite mass was subjected to three milling and two calcining operations. Specimen sintering conditions were investigated in a KO-14 furnace placed in an autoclave. Heating and cooling were performed in a vacuum. Microstructural analysis was carried out with an MMR-2R microscope. Static magnetic parameters were measured, using a ballistic apparatus with an F190 microwebermeter. (7 refs.)

73050 Hot-pressed oxynitrides in the system AlN-Al_2O_3. T.Sakai (Nat. Inst. for Res. in Inorganic Materials, Ibaraki, Japan).
Sintering - Theory and Practice. Proceedings of the 5th International Round Table Conference on Sintering, Portoroz, Yugoslavia, 7-10 Sept. 1981 (Amsterdam, Netherlands: Elsevier 1982), p.591-6
The alumina addition more than 2.5 mol.% in the system AlN-alumina leads to densify more than 99% of theoretical density by hot pressing. Oxynitride of spinel structure was found in the whole composition range in this system in the compact hot-pressed at 1650°C. Spinel reacted with AlN to form five pseudopolytypes AlN at above 1850°C. Thermal conductivities of the compacts were influenced by not only the amount of oxygen but also crystal structure of second phase in the compact intensely. High temperature flexural strength of the AlN compact was improved with addition of 5-15 mol.% alumina and the compact was composed pseudopolytype AlN after hot pressing at 1900°C. When the concentration of the AlN composition in the oxynitride of spinel was well controlled, the compact could have a good infrared transmittance. (7 refs.)

73051 Hot pressing and properties of different Si_3N_4 qualities. G.Grathwohl (Inst. fur Werkstoffkunde, Univ. Karlsruhe, Karlsruhe, Germany), S.B.Hanna, F.Thummler.
Sintering - Theory and Practice. Proceedings of the 5th International Round Table Conference on Sintering, Portoroz, Yugoslavia, 7-10 Sept. 1981 (Amsterdam, Netherlands: Elsevier 1982), p.597-604
α-Si_3N_4 powders of high activity (11-14 m^2/g) are available either from industry or by ball milling of conventional powders in Si_3N_4-lined vessels. The improved hot pressing behaviour of thse powders has been investigated with and without MgO additions. Full densification can be achieved with extremely small amounts of MgO (<0.1%), when this is added in form of a contamination during the milling process; 0.3-0.4% MgO are necessary when normal mixing procedure is applied. The resulting microstructures are dependent on the amount of additives. Oxidation, strength and creep properties are presented and discussed. (12 refs.)

73052 Fabrication of non-oxide ceramics by hot isostatic pressing. T.Yamada, M.Shimada, M.Koizumi (Inst. of Sci. & Industrial Res., Osaka Univ., Osaka, Japan).
Sintering - Theory and Practice. Proceedings of the 5th International Round Table Conference on Sintering, Portoroz, Yugoslavia, 7-10 Sept. 1981 (Amsterdam, Netherlands: Elsevier 1982), p.605-10
Hot isostatic pressing of highly pure Si_3N_4 and TiN were performed at 100-200 MPa and 1100-1900°C, and effects of pressure/temperature/time parameters on densification were studied. Highly pure α-Si_3N_4 powders could be densified at 94% theoretical density without additives, when $\alpha \rightarrow \beta$ phase transformation occurred. A fine grained and highly dense TiN ceramic body was fabricated without additives, using submicron powders as starting materials. (10 refs.)

73053 Sintering of PZT ceramics. I. Atmosphere control. A.I.Kingon, J.B.Clark (Nat. Phys. Res. Lab., CSIR, Pretoria, S Africa).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.253-6 (April 1983).
Methods of PbO atmosphere control during the sintering of PZT ceramics are briefly reviewed. The problem of atmosphere control of PZT compositions containing a PbO excess ($PbO/(Zr,Ti)O_2 > 1$) is discussed. Weight-loss experiments were performed to compare with behavior predicted by reference to the PbO-rich part of the ternary PbO-ZrO_2-TiO_2 phase diagram. The results indicated that the PbO activity of a PZT composition is a function of the excess PbO content, contrary to earlier reports. Experimental procedures were established in order to control the PbO content within satisfactory limits. The effects of various packing powders on the PbO content of sintered PZT compacts were evaluated. (13 refs.)

73054 Partially stabilized zirconia. S.Yuuhaku, H.Okinaka, H.Torii, T.Miyazawa (Wireless Res. Lab., Matsushita Electric Industrial Co. Ltd., Osaka, Japan).
Natl. Tech. Rep. (Japan), vol.29, no.1, p.154-62 (Feb. 1983). In Japanese.
A partially stabilized zirconia is a solid electrolyte body which functions as an oxygen sensor for an automobile engine system, because it has high resistance to mechanical stress and thermal shock. However, it has the drawback that the resistance is remarkably small when it is held at a certain low temperature, such as about 200°C. In order to remove this drawback, basic materials and preparation process of the material were investigated. It was found that two preparation conditions are important for improvement of the drawback: addition of MgO, CaO and SiO_2 to a partially stabilized zirconia by 5 mol% of Y_2O_3; repetition of calcination-crushing cycle. The partially stabilized zirconia ceramic obtained under the above preparation conditions has a high bending strength (30 $kg.mm^{-2}$), and withstands highly thermal shock (170 deg). Furthermore, even if the ceramic is held at 200°C for 500 h, its bending strength still remains high. (11 refs.)

73055 Effect of application of ultrasound during pressing on the structure of tungsten carbide base materials. L.T.Buchek, I.G.Tereshchenko (Correspondence Polytech. Inst., Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.712-14 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.35-8 (Sept. 1982). [received: March 1983]
An investigation was carried out to determine the effect of USV on the structure of WC base compacts. The action of USV applied during pressing comminuted the tungsten carbide particles and decreased the porosity of the compact and hence the volume of infiltrating material, which brought about an increase in density. Application of USV promoted a more uniform distribution of the components in VK15 compacts. (4 refs.)

73056 Electrical resistivity, magnetoresistance and microstructure of carbon-fiber/CVD-carbon composite. S.Kimura (Res. Lab. of Engng., Materials, Tokyo Inst. of Technol., Yokohama-shi, Japan), T.Hagio, E.Yasuda, Y.Tanabe, Y.Hishiyama, Y.Kaburagi.
Yogyo-Kyokai-Shi (Japan), vol.91, no.3, p.121-5 (1983). In Japanese.
Three types of carbon-fiber/CVD-carbon composite, in which carbon matrix was isotropic (ISO), rough columnar (RC) or smooth columnar (SC), were prepared at 1300°C by chemical vapor deposition from propane-hydrogen mixtures. The electrical resistivites of the as-deposited composites were 2.1×10^{-3}, 1.0×10^{-3} and 1.6×10^{-3} Ω.cm for ISO, RC and SC composites, respectively. The transverse magnetoresistances of all these composites showed negative values at 4.2K. The electrical resistivities of their 3000°C heat-treated products were 1.2×10^{-3}, 0.3×10^{-3} and 0.6×10^{-3} Ω.cm, respectively. The value of the transverse magnetoresistances of the heat-treated RC and SC composites were positive at 77K, but that of ISOP composite was negative. The results indicate that all the the as-deposited CVD carbon are turbostatic in structure, and the ISO carbon is non-graphitizing, while the other two, especially RC carbon is easily graphitizing. (16 refs.)

73057 The kinetics of densification of binary titanium-chromium diboride with copper-nickel binder. M.S.Koval'chenko, L.F.Ochkas (Inst. for Problems of Materials Sci., Acad. of Sci., Kiev, Ukrainian SSR).
Sintering - Theory and Practice. Proceedings of the 5th International Round Table Conference on Sintering, Portoroz, Yugoslavia, 7-10 Sept. 1981 (Amsterdam, Netherlands: Elsevier 1982), p.619-24
An experimental study was carried out of densification kinetics for powder mixtures of titanium-chromium diboride with copper-nickel binder during hot pressing. As a result of the analysis of the kinetics above in the framework of volume viscous flow theory the porous solid densification is shown to be affected by nonlinear steady-state creep with dependence of solid flow rate on quadrate of stress. Activation energy was evaluated regularly decreasing from 2,8 to 2,0 eV as binder content rising in alloys of titanium-chromium diboride. The mechanism is discussed briefly. (11 refs.)

81.20P Glasses

73058 Silicon-free oxynitride glasses via nitridation of aluminate glass-melts. L.M.Bagaasen, S.H.Risbud (Dept. of Ceramic Engng., Univ. of Illinois, Urbana, IL, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.C69-71 (April 1983).
Aluminate-oxynitride glasses were synthesized by melting calcium-aluminate-based compositions with various amounts of AlN in a nitrogen atmosphere. X-ray amorphous Ca-Al-Mg-Ba-O-N oxynitride glasses free of metallic inclusions containing up to ≈1 at.% N were obtained. Nitride additions increased the glass transition temperatures while decreasing thermal expansion, as in other Si-containing oxynitride systems. (9 refs.)

73061 Preparation, electrical resistivity and its temperature dependence of RuO_2-polystyrene composite powder. T.Nishizawa, M.Senna, H.Kuno (Faculty of Sci. & Technol., Keio Univ., Yokohama, Japan).
J. Mater. Sci. (GB), vol.18, no.5, p.1346-52 (May 1983).
RuO_2-polystyrene composite powder was prepared by admixing fine powdered RuO_2 and polystyrene beads thoroughly in ethanol. RuO_2-coated polystyrene beads were also prepared by direct suspension polymerization of styrene in an aqueous phase in the presence of a suspended RuO_2 powder. The apparent d.c. volume resistivity, hot-pressed composite was measured at various temperatures (20 to 80°C), pressures (3.5 to 35 MPa) and volume fractions of RuO_2, ϕ, (0.008 to 0.10). The volume resistivity increased linearly with temperature on a double logarithmic scale. The equilibrium volume resistivity at constant temperature, ρ_{aT}, decreased remarkably when ϕ increased from 0.025 to 0.04 for the mixed material, due to the establishment of a continuous network of RuO_2 in this region, as revealed by scanning electron microscopy. The composite prepared by direct polymerization completed a network of the conductive phase at a much smaller volume fraction of RuO_2. The average size of RuO_2 aggregates covering the surface of polystyrene agreed fairly well with the calculated value based on the simple geometry. (7 refs.)

73062 Alkali treatment of coir fibres for coir-polyester composites. S.V.Prasad, C.Pavithran, P.K.Rohatgi (Regional Res. Lab., Council of Sci. & Industrial Res., Kerala, India).
J. Mater. Sci. (GB), vol.18, no.5, p.1443-54 (May 1983).
Coir fibres were subjected to alkali treatment with a view to improving the wettability of coir fibres by a commercially available resin such as polyester. Tensile strength of the fibres increases by 15% when the fibres are soaked in 5% aqueous solution of NaOH at 28±1°C for 72 to 76 h after which it shows a gradual decrease. This decrease is much more pronounced when the alkali is replenished after every 24 h. SEM observations showed the removal of cuticle and tyloses from the surface of coir as a result of alkali treatment, resulting in a rough fibre surface with regularly spaced pits. The debonding stress of alkali-treated fibres from polyester matrix was 90% higher than that of untreated fibres from the same matrix. Incorporation of 0.30 volume fraction of untreated and treated fibres in polyester resulted in composites having 11% and less 5% porosity, respectively. Flexural strength, modulus and impact strength of composites containing alkali-treated fibres in polyester resulted in composites having 11% and less 5% porosity, respectively. Flexural strength, modulus and impact strength of composites containing alkali-treated fibres were 40% higher than those containing the same volume fractions of untreated fibres. Longitudinal ultrasonic velocity and sound attenuation measurements indicated less fibre segregation and better fibre-matrix bonding in composites containing alkali-treated fibres. (11 refs.)

73063 Isotropy of spinodal decomposition in Fe-30% Cr. S.Spooner, W.E.Brundage (Solid State Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
Scr. Metall. (USA), vol.17, no.4, p.573-4 (April 1983).
The authors report the results of neutron scattering measurements made on a single crystal of iron-30% chromium which has been decomposed within the spinodal region of the miscibility gap. (9 refs.)

73064 A theoretical analysis of the phase-decompositions based upon the non-linear diffusion equation. T.Miyazaki, T.Kozakai (Dept. of Metall. Engng., Nagoya Inst. of Technol., Nagoya, Japan), S.Mizuno, M.Doi.
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.246-54 (April 1983).
A general form of the Fourier expression for the Cahn-Hilliard's flux equation is proposed, in which two kinds of the non-linear terms follow the linear term developed by Cahn, and computer-simulations for the time developments of phase-decompositions in some supersaturated solid solutions are derived on the basis of the Fourier expression. The phase-decompositions proceed to form periodic zone-arrangements in the high solute alloys, while in the low solute alloys a few composition peaks sparsely distributed appear. The diffusion-behaviors simulated for the phase-decompositions seem to be essential for the basic understanding on the formations of microstructures. (10 refs.)

73065 Formation of rutile type solid solutions in pseudobinary systems SnO_2-ABO_4 (A=Ga, Cr; B=Nb, Ta, Sb^{5+}) and SnO_2-AB_2O_6 (A=Mg, Zn; B=Sb^{5+}). T.Kikuchi, A.Watanabe, K.Uchida (Nat. Inst. for Res. in Inorganic Materials, Ibaraki, Japan).
Yogyo-Kyokai-Shi (Japan), vol.91, no.3, p.110-16 (1983).
Rutile type solid solutions in both SnO_2-ABO_4 (A=Ga, Cr; B=Nb, Ta, Sb^{5+}) systems and SnO_2-AB_2O_6 (A=Mg, Zn; B=Sb^{5+}) systems were synthesized and their lattice parameters were investigated in each system. A complete series of solid solutions were found in the SnO_2-$GaSbO_4$ system at 1200°C and in the SnO_2-$CrNbO_4$ system at 1350°C. $CrSbO_4$ was soluble in SnO_2 up to 80 mol.% as the form of $A_{0.5}B_{0.5}O_2$ at 1200°C. Similarly, $GaNbO_4$ and $GaTaO_4$ were soluble up to 50 mol.% and up to 85 mol.% at 1300°C, respectively. In all cases, lattice parameters decreased with decreasing SnO_2 content. Sb-oxides dissolved in SnO_2 in air at 1200°C up to 2.3 atomic % expressed with Sb/(Sn+Sb). The lattice parameters of the sample with 2.3 atomic% Sb were $a=4.740\pm0.001$ Å and $c=3.190\pm0.0005$ Å. $ZnSb_2O_6$ (trirutile structure) was soluble in SnO_2 up to 50 mol.% as the form of $Zn_{1/3}Sb_{2/3}O_2$ at 1200°C; whereas SnO_2 dissolved in $Zn_{1/3}Sb_{2/3}O_2$ up to 20 mol.% at the same temperature. The lattice parameters decreased with decreasing SnO_2 content. Similarly, $MgSb_2O_6$ dissolved in SnO_2 up to 50 mol.% at 1250°C but SnO_2 was little soluble in $MgSb_2O_6$. (16 refs.)

81.30B Phase diagrams of metals and alloys

73066 Diagram of state for the Yb-Ge system. V.N.Eremenko, K.A.Meleshevich, Yu.I.Buyanov.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.3, p.83-8 (1983). In Ukrainian.
The structure of ytterbium-germanium alloys is studied by metallographic, chemical, X-ray and thermal analyses. For the first time the phase diagram is plotted. (8 refs.)

73067 Phase equilibria in iron ternary systems. V. Critical evaluation of constitutions of certain ternary alloys containing iron, tungsten, and a third metal. [addendum]. G.V.Raynor, V.G.Rivlin (Dept. of Metall. & Materials, Univ. of Birmingham, Birmingham, England).
Int. Met. Rev. (GB), vol.28, no.2, p.122-9 (1983).
For original work see ibid., vol.26, p.213-49 (1981). Work on the systems Fe-W and Fe-W-Ni, too recent to have been considered in the authors' assessment of the constitutions of ternary alloys based on iron and tungsten, has thrown new light on the nature of the equilibria in these systems. In this addendum the new work and its implications are described. The opportunity has also been taken to present additional data on certain aspects of the constitution of Fe-W-Cr alloys. (17 refs.)

73068 Calculation of the liquidus surface of the Ti-Mo-Al system. V.M.Danilenko, A.A.Rubashevskii (Inst. of Materials Sci., Acad. of Sci., Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.722-4 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.46-9 (Sept. 1982). [received: March 1983]
The results are presented of a calculation of the liquidus surface of the system under consideration, made with the aid of a model of subregular solutions. (5 refs.)

73069 Phase equilibria in the Sm-Re-B system. S.I.Mikhalenko, Yu.B.Kuz'ma, O.K.Shchur (Lvov State Univ., Lvov, Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.725-7 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.50-2 (Sept. 1982). [received: March 1983]
Presents a study of the phase equilibria and a search for new compounds in the Sm-Re-B system, using published information on the binary systems Sm-B, Re-B, and Sm-Re. In all, 120 specimens were prepared for investigation. The specimens were subjected to X-ray phase analyses and metallographic examinations. X-ray photographs were taken, using chromium radiation, in 57.3-mm-diameter Debye cameras. Microstructures were studied visually with an MIM-7 metallographic microscope. The results of phase analyses of the specimens were used for constructing an isothermal section of the Sm-Re-B constitution diagram at 1270K. (15 refs.)

73070 A thermodynamic analysis of the tin-tellurium system and calculation of the phase diagram. K.-C.Hsieh, M.S.Wei, Y.A.Chang (Dept. of Metall. & Mineral Engng., Univ. of Wisconsin-Madison, Madison, WI, USA).
Z. Metallkd. (Germany), vol.74, no.5, p.330-7 (May 1983).
The thermodynamic data of liquid Sn-Te alloys are analyzed in terms of an associated solution model in this model, it is postulated that 'SnTe' species exists in the liquid in addition to 'Sn' and 'Te'. This model with eight parameters quantitatively describes the thermodynamic data of the liquid alloys over a wide range of composition and temperature. These eight parameters consist of two for the temperature dependence of the association equilibrium constant and six for the interactions of 'Sn'-'SnTe' and 'SnTe'-'Te'. The Darken excess stability function for the liquid phase shows a pronounced maximum near 50 at.% Te. All three thermodynamic functions the Gibbs energy, enthalpy and entropy, show sharp minima also at 50 at.% Te. Based on the thermodynamic properties of the liquid alloys evaluated from the model and those of other phases in the system, the Sn-Te phase diagram is calculated. (47 refs.)

73071 Stable and metastable phase relations in the system ZrO_2-CaO. J.R.Hellmann, V.S.Stubican (Dept. of Materials Sci. & Engng., Pennsylvania State Univ., University Park, PA, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.260-4 (April 1983).
The chemical equilibrium for the system ZrO_2-CaO was redetermined for temperatures above $\approx$1000°c by heating reactive powders for extended periods of time. The eutectoid decomposition of the cubic solid solution was found to occur at 1140°±40°C and 17.0±0.5 mol% CaO. Decomposition reactions in sintered cubic solid solutions were studied using electron diffraction and transmission techniques. Decomposition follows metastable extensions of the boundary lines which separate two-phase regions from the adjacent cubic solid solution region. The appearance of the diffuse diffraction features in the electron diffraction patterns of cubic solid solutions seems to be associated with short-range ordering of oxygen vacancies. Two ordered phases, $CaZr_4O_9$ and $Ca_6Zr_{19}O_{44}$, were synthesized and their upper limits of stability were determined to be 1235°±15° and 1355°±15°C, respectively. (18 refs.)

73072 Phase relations and ordering in the systems MgO-Y_2O_3-ZrO_2 and CaO-MgO-ZrO_2. J.R.Hellmann, V.S.Stubican (Dept. of Materials Sci. & Engng., Pennsylvania State Univ., University Park, PA, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.265-7 (April 1983).
The phase relations in the systems MgO-Y_2O_3-ZrO_2 and CaO-MgO-ZrO_2 were established at 1220° and 1420°C. The system MgO-Y_2O_3-ZrO_2 possesses a much-larger cubic ZrO_2 solid solution phase field than the system CaO-MgO-ZrO_2 at both temperatures. The ordered δ phase $(Zr_3Y_4O_{12})$ was found to be stable in the system ZrO_2-Y_2O_3 at 1220°C. Two ordered phases ϕ_1 $(CaZr_4O_9)$ and ϕ_2 $(Ca_6Zr_{19}O_{44})$ were stable at 1220°c in the system ZrO_2-CaO. At 1420°C no ordered phase appears in either system, in agreement with the previously determined temperature limits of the stability for the δ, ϕ_1, and ϕ_2 phases. The existence of the compound $Mg_3Y_2O_6$ could not be confirmed. (27 refs.)

73073 The correlation of the thermodynamic properties of wustite by a gaussian based formalism. J.D.Esdaile (Div. of Mineral Engng., CSIRO, Clayton, Victoria, Australia).
Metall. Trans. A (USA), vol.14A, no.4, p.771-5 (April 1983).
A Gaussian-based formalism is used to correlate precisely the data of Darken and Gurry (1945) for the wustite phase of the industrially important system Fe-O within and at the boundaries of this phase. Equations are also given for the free energy and heats of formation of metastable FeO, wustite in equilibrium with γ-Fe, and Fe_3O_4 from γ-Fe and oxygen at 1 atm. (7 refs.)

73074 The ternary system CaF_2-CdF_2-CrF_3. Dimorphism of $CaCrF_5$ and CrF_3. M.Samouel, A.de Kozak (Lab. de Chimie Minerale, Univ. Pierre et Marie Curie, Paris, France).
Rev. Chim. Miner. (France), vol.20, no.1, p.37-44 (1983). In French.
The liquid-solid equilibria diagrams of the system CaF_2-CrF_3 and of the ternary system CaF_2-CdF_2-CrF_3 are established by DTA and X-ray investigation. Three definite compounds ($CdCrF_5$, $CaCrF_5$, Ca_2CrF_7) and three non-stoichiometric phases ($Cd_{1-x}Ca_xF_2$, $Cd_{1-x}Ca_xCrF_5$, $Ca_{2-2x}Cd_xCrF_{7-2x}$) are disclosed and studied. The dimorphism of $CaCrF_5$ and CrF_3 is established. (17 refs.)

73075 Some physical aspects of unidirectional crystallisation in microgravity. V.S.Avduyevsky, S.D.Grishin, L.V.Lescov (Intercosmos Council, Acad. of Sci., Moscow, USSR).
Acta Astronaut. (GB), vol.9, no.9, p.583-8 (Sept. 1982). [received: March 1983]
Deals with the analysis of physical features of ingot fabrication with the aid of a unidirectional crystallisation method in microgravity. Conditions were investigated under which the main contribution to the process of heat and mass transfer in the melt would be made by the convection induced by the Marangoni effect. To estimate the thickness of typical boundary layers and the current rate values analytical correlations have been obtained. The effect of heat exchange features in the melt on the crystallisation front rate value has been treated. To demonstrate experimentally the unidirectional crystallisation of germanium in space the distribution of alloying admixtures has been calculated and the distribution density estimates have been made. (12 refs.)

73076 Microsegregation and extended solid solutions after rapid solidification of aluminium alloys. L.Katgerman (Lab. for Metall., Delft Univ. of Technol., Delft, Netherlands).
Scr. Metall. (USA), vol.17, no.4, p.537-40 (April 1983).
A criterion for segregation cellular solidification is formulated, based on the thermodynamic requirement in combination with a kinetic approach of the solidification process. This treatment results in more realistic values for the critical solidification rate for complete solid solutions and in predictions of extended solid solubilities as a function of solidification rate. (17 refs.)

73077 Formation and stability of extended solid solutions made by rapid quenching from the melt. H.Jones (Dept. of Metall., Univ. of Sheffield, Sheffield, England).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.71-7
Extension of solid solubility by rapid quenching from the melt (RQM) enormously increases the scope for alloy development in metals such as aluminium for which solid solubility is particularly limited under equilibrium conditions. The author mainly reviews recent work concerned with matching of experimental observations with predictions affecting: (1) conditions for solidification without change in composition, (2) temperatures and modes of decomposition on subsequent heating, and (3) hardening effects as-quenched and on heat treatment. The significance of such findings for bulk production and consolidation of wrought products for engineering applications is briefly discussed. (40 refs.)

73078 Rapid solidification of metastable materials. H.Liebermann, J.Walter (General Electric Corporate Res. & Dev., Schenectady, NY, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.111-22
There are numerous processing methods available for the fabrication of rapidly-solidified metastable alloys. Examples include splat quenching, melt-spinning, surface melting and quenching, melt atomization and solidification, and deposition by sputtering and evaporation. Experimental aspects of each of these fabrication methods are discussed. These include solidification and quench rate, process control, and final product morphology and microstructure. Some properties of an amorphous alloy prepared by several of these processing methods are discussed. (102 refs.)

73079 Rapid solidification—mechanisms, morphology and microstructure. J.A.Domingue, W.J.Boesch (Special Metals Corp., New Hartford, NY, USA), J.F.Radavich, K.O.Yu.
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.161-5
Two nickel base disk alloys, Rene' 95 (R-95) and Inconel 100 (IN-100) were studied. The R-95 was manufactured by argon gas atomization (AA) and by centrifugal or spinning cup atomization (CA). AA IN-100 from SMC was studied as was IN-100 manufactured by an advanced rapid solidification rate (RSR) technique. V-60, a nickel base plasma spray hard facing alloy, manufactured by water atomization (WA), was also studied. Noticeable differences are observed between RSR and AA superalloy powders, but secondary dendrite arm spacing, thermograms and density become more similar as particle size decreases into the range normally used for further processing. (6 refs.)

73080 High-temperature X-ray investigation of conversion of cementite into austenite. V.M.Ershov (Mining-Metall. Inst., Kommunar, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.605-7 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A special high-temperature X-ray method was developed for a detailed study of the process of conversion in some pure metals (Fe, Ni, Co, Ti) containing embedded silicon carbide (cementite) particles. Heating caused conversion of the carbide phase to austenite and at elevated temperatures (above 500°C) the metastable austenite became saturated with the alloying element (for example, nickel) and was thus stabilized. (3 refs.) *A.T.*

73081 Considerations of solute-drag in relation to transformations in steels. H.K.D.H.Bhadeshia (Dept. of Metall. & Materials Sci., Univ. of Cambridge, Cambridge, England).
J. Mater. Sci. (GB), vol.18, no.5, p.1473-81 (May 1983).
In recent years, solute-drag theory has been widely quoted to explain apparent discrepancies in kinetic measurements of transformations in steels. Since conventional impurity drag theory is concerned solely with drag at grain boundaries, many new, or 'special' drag models have been developed to apply at interphase interfaces. An assessment is made of these special drag theories, and of the experimental evidence claimed in their support. It is found that our understanding of solute-drag at interphase interfaces is very weak, and that the experimental evidence for the existence of solute drag at transformation interfaces in steels is very doubtful. 73082 Influence of hydrogen on the temperature of a thermoelastic martensitic transformation in titanium nickelide. I.A.Stepanov, Yu.M.Flomenblit, V.A.Zaimovskii (All-Union Interdisciplinary Sci.-Res. Inst. on Protection of Metals from Corrosion, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.612-14 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Samples were subjected to electrochemical hydrogenation in a 4% solution of sulphuric acid. The temperature of the investigated transformation rose to a maximum and then fell as the hydrogenation treatment was continued. The results also depended on the current density during the hydrogenation treatment. (5 refs.) *A.T.*

73083 A transformation anomaly in a Cu-Zn-Al alloy. W.M.Stobbs (Dept. of Metall. & Materials Sci., Univ. of Cambridge, Cambridge, England).
J. Microsc. (GB), vol.129, pt.3, p.307-14 (March 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
A comparison is described of the structures of an M9R Cu-Zn-Al alloy as quenched directly into the martensitic state, and as stabilized, with the structure of the material after up-quenching into the β_1 state after which treatment the martensitic memory transformation occurs thermoelastically. Preliminary results on the increased tendency for the stabilized alloy to form FCC stacking sequence regions are given and discussed. (5 refs.)

73084 Characteristic martensitic transformation of the Fe-Pt disordered alloys around the γ-α phase boundary. K.Sumiyama, M.Shiga, Y.Nakamura (Dept. of Metal Sci. & Technol., Kyoto Univ., Kyoto, Japan).
Phys. Status Solidi a (Germany), vol.76, no.2, p.747-51 (16 April 1983).
Magnetization and thermal expansion are measured for Fe-26 and 27 at.% Pt disordered alloys. A martensitic transformation with a large hysteresis is detected for the Fe-26 at.% Pt disordered alloy, whose M_s temperature is just below the Curie temperature of the FCC phase. On the other hand, a martensitic transformation with a small hysteresis, which can be classified as a thermoelastic transformation, is observed for the Fe-27 at.% Pt disordered alloy, whose M_s temperature is much lower than the Curie temperature of the FCC phase. Since the positive volume magnetostriction (Invar effect) becomes large above the M_s temperature for the Fe-27 at.% disordered alloy, it may play an important role in determining favourable conditions for the thermoelastic martensite transformation in the Fe-Pt alloys. 73085 Investigation of coalescence processes in Al-2.8% Li alloy. A.L.Berezina, L.N.Trofimova, K.V.Chuistov (Inst. of Metal Phys., Acad. of Sci., Kiev, Ukrainian SSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.543-7 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Kinetics of precipitation of Al-2.8% Li alloy after quenching to the ageing temperature was investigated by an analysis of the evolution of the particle size distribution curve. The growth of the average particle size was described by a cubic function of time. The form of the distribution curves corresponded, as indicated by a check against the Pearson criterion, to the theoretical Lifshiftz-Slezov distribution. The activation energy of the process of coalescence of the δ'-phase ($Q=-117$ kJ/mole) was determined and the surface energy of coherent particles of the δ'-phase was found ($\gamma=0.087$ J/m^2). (14 refs.) *A.T.*

73086 Influence of two-stage ageing on structural transitions in β-zirconium alloys. M.I.Zakharova, V.B.Vasil'eva (M.V. Lomonosov State Univ., Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.619-22 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An investigation was made of the influence of two-stage ageing on the precipitation of the b.c.c. β solid solution in zirconium alloys with the compositions 74% Zr, 14% Nb, 12% Mo or 68% Zr, 23.3% Nb, 8.5% Mo (all atomic percent). X-ray structure analysis and diffraction electron microscopy were used in this study. Various precipitation processes were observed in the two alloys. (2 refs.) *A.T.*

73087 The precipitation of tungsten hemi-carbide (W_2C) in tungsten wafers. T.Epicier, C.Esnouf (Inst. Nat. des Sci. Appliquees, Villeurbanne, France).
J. Less-Common Met. (Switzerland), vol.90, no.2, p.L31-3 (April 1983). In French.
The communication reports the results of work in which tungsten wafers (25×4×0.3 mm), made by electrolytic polishing and ionic bombardment were carburised by being surrounded by graphite pellets at 2000°-2100°C for several minutes, the amount of carbon so introduced varying from 1 per thousand to several percent (atomic). The reported observations confirm previous results on the precipitation of the hexagonal phase of Me_2C obtained by transmission electron microscopic observation of a variety of metals. Illustrated are the appearance of an incoherent precipitate, surrounded by helical dislocations and the presence of the W_2C phase together with its orientation in the matrix, all being consistent with the relations found by Burgers. Successive stages of the precipitation were observed qualitatively in different specimens, all suggesting that the precipitation of the W_2C in the tungsten operates in the same way as in other systems of transition metal and carbon. Further work is required to clear up some finer points concerning deviation of axes. (11 refs.) *C.J.O.G.*

73088 The kinetics of σ-phase precipitation in AISI 310 and AISI 316 steels. J.Barcik (Inst. of Phys. & Chem. of Metals, Silesian Univ., Katowice, Poland).
Metall. Trans. A (USA), vol.14A, no.4, p.635-41 (April 1983).
The kinetics of σ-phase precipitation in AISI 310 and AISI 316 steels were studied. An attempt was made to express the rate of precipitation of σ-phase with formal kinetic theory equations. It was established that rate of precipitation of σ-phase is a function of temperature that agrees with the Johnson-Mehl equation. (24 refs.)

73089 Segregation to interphase boundaries in liquid-phase sintered tungsten alloys. C.Lea (Div. of Materials Applications, NPL, Teddington, England), B.C.Muddle, D.V.Edmonds.
Metall. Trans. A (USA), vol.14A, no.4, p.667-77 (April 1983).
Scanning Auger electron spectroscopy has been used to examine the distribution of impurity elements on the fracture surfaces of liquid-phase sintered W-Ni-Cu and W-Ni-Fe alloys. On the interphase boundaries between the FCC Ni-based matrix phase and the tungsten particles, segregation levels of ~0.4 and ~0.2 monolayers of phosphorus have been observed in as-sintered, furnace-cooled specimens of W-Ni-Cu and W-Ni-Fe, respectively. The phosphorus is homogeneously distributed but at fracture adheres preferentially to the matrix phase. High temperature heat treatment (1350°C) followed by water quenching reduces significantly the phosphorus segregation and improves the degree of cohesion across these boundaries. Segregated sulfur is detected on both sides of the interphase boundaries after fracture. The sulfur is much less uniformly distributed than the phosphorus, and its segregation level increases in the heat treated specimens. Copper also segregates to the interphase boundaries during the heat treatment of W-Ni-Cu specimens, but no equivalent segregation of iron was observed in the W-Ni-Fe system. The boundaries developed between adjacent tungsten particles are free of impurity contamination in both alloy systems but have a segregated layer of nickel. (25 refs.)

73090 High-resolution electron microscopy study of a Ti-1.6 at.% N alloy. D.Sundararaman, A.L.E.Terrance (Reactor Res. Centre, Kalpakkam, India), G.van Tendeloo, J.van Landuyt.
Phys. Status Solidi a (Germany), vol.76, no.2, p.K109-11 (16 April 1983).
Direct lattice imaging with a high-resolution TEM is a powerful technique for complementing crystal structure determination and specifically suited to the study of mixed structures. The authors present a high-resolution electron microscopy study of the ordered zones (α') that are present in the supersaturated α''(HCP) and its subsequent transformation on ageing to Ti_2N precipitates. (4 refs.)

73091 The sequence of phases in Al-Cu alloys. T.B.Wu (Dept. of Materials Sci. & Engng., Nat. Tsing Hua Univ., Hsinchu, Taiwan), E.Matsubara, J.B.Cohen.
Scr. Metall. (USA), vol.17, no.4, p.559-62 (April 1983).
The approach to equilibrium upon ageing of Al-Cu alloys is studied by X-ray diffraction. The sequence of phases are identified. Guinier-Preston zones I and II are observed from the diffraction peaks. A mechanism is discussed in terms of the elastic energy of a solid solution. Phonon dispersion curves are illustrated. (10 refs.)

73092 Some aspects of micro-alloying. R.W.K.Honeycombe (Univ. of Cambridge, Cambridge, England).
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.177-89 (April 1983).
The various basic roles of micro-alloying additions are examined within a framework which emphasizes their modes of distribution in alloys. The effects of solute atoms when segregated to vacancies, dislocations and grain boundaries are briefly reviewed. The formation of precipitates involving micro-additions are shown to influence markedly the behaviour of many alloys. Examples are given of the effects of solute atoms in the nucleation and growth of phases in both ferrous and non-ferrous alloys. Another important

field is illustrated by the control of grain growth and recrystallization by micro-alloying additions to achieve ultra-fine grain sizes, for example in aluminium alloys to obtain superplastic behaviour, and in HSLA steels to obtain high strength and toughness. Some examples are also given of the effects of micro-alloying in phase transformations, particularly nucleation of precipitates at interphase boundaries. Finally, some beneficial effects of minor additions made to creep-resistant nickel-base and Cr-Ni austenitic alloys are discussed. (31 refs.)

73093 Defect interactions in 'solar' silicon. D.Helmreich, H.Seiter (Heliotronic, Burghausen, Germany), D.Huber, R.Wahlich.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.405-10
In poly-Si the appearance of SiC and SiO_x precipitates is correlated with the thermal history and the carbon and oxygen content. Oxygen precipitation seems to play a distinct role in the formation of denuded zones along high-energy incoherent grain boundaries. EBIC studies on zones of this kind show unusual electrical behaviour that will be investigated further. (26 refs.)

73094 Microsegregation of an aluminum and magnesium alloy at high solidification rates. L.J.Masur, J.T.Burke, T.Z.Kattamis, M.C.Flemings (MIT, Cambridge, MA, USA).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.185-9
Results are presented of an on-going study of structure and solute redistribution in ribbon cast Al-Cu and Mg-Zn alloys. Regions found in these ribbons are (1) an apparently chemically homogeneous coarse-grained zone adjacent to the chill, (2) a transition cellular region, and (3) a dendritic zone, usually equiaxed. In both alloys, structure in the equiaxed region becomes coarser with increasing distance from the chill. In Mg-Zn alloys, the amount of nonequilibrium second phase increases essentially linearly with distance in the cellular and dendritic regions. Scanning transmission electron microscopy can accurately measure solute distribution across rapidly solidified cells or dendrites, but the possibility of surface compositional changes during specimen preparation must be recognized. 81.40 TREATMENT OF MATERIALS AND ITS EFFECTS ON MICROSTRUCTURES AND PROPERTIES

73095 A comparison of probabilistic techniques for the strength of fibrous materials under local load-sharing among fibers. S.L.Phoenix (Sibley School of Mech. & Aerospace Engng., Cornell Univ., Ithaca, NY, USA), R.L.Smith.
Int. J. Solids & Struct. (GB), vol.19, no.6, p.479-96 (1983).
Compares three distinct asymptotic analyses for the probability distribution for strength of a certain class of fibrous materials. This class, which contains composite materials and twisted yarns and cables, is characterized by strong, mechanical interaction among neighboring fibers as is generated by a binding matrix or by transverse frictional forces. The model is the chain-of-bundles model, and the authors focus mainly on a planar geometry and a simple type of local load-sharing among fibers in a cross-section wherein the load of a failed fiber is shifted in equal portions to its two nearest flanking survivors. Through the study of typical examples the authors find that the results of the three methods all underscore the importance of the Weibull distribution for modeling composite strength, and are in excellent numerical agreement despite their differing analytical form. This is fortunate because only the two least accurate of the analysis show promise of being extended to more general three-dimensional geometries and local load-sharing rules of interest in applications. (19 refs.)

73096 Effect of silane coupling agents on mechanical and thermal properties of polyester resin concrete. P.Mani, A.K.Gupta, S.Krishnamoorthy (Centre for Materials Sci. & Technol., Indian Inst. of Technol., New Delhi, India).
J. Mater. Sci. (GB), vol.18, no.5, p.1506-14 (May 1983).
Polyester resin-quartzite aggregate composites have been investigated for the effect of two silane coupling agents (γ-aminopropyl triethoxy silane and γ-methacryloxy propyl trimethoxy silane) on the mechanical and thermal properties. The integral blend additive method of application of the coupling agent was used in the preparation of the samples. Variation of the thermal stability and the compressive strength with the nature and the content of the silane coupling agent were quite consistent. The properties showed maxima around a certain value of the coupling agent content, which is suggested as the optimum value. Results are also presented on the samples containing an additional filler, namely, the $CaCO_3$. (10 refs.)

73097 A rational method for calculating mechanism maps. J.K.McCoy (Battelle, Columbus Labs., Columbus, OH, USA).
Scr. Metall. (USA), vol.17, no.4, p.563-8 (April 1983).
Methods for the systematic calculation and plotting of mechanism maps are described. It is discussed in terms of deformation modelling but the methods may be applied to other problems. The first step in the construction of the map is to divide the map into regions of dominance of mechanism. The second step is to find a set of contour lines for each of the regions. The third step is to plot the boundaries of the regions and the contours in a smooth and efficient manner. Examples are presented which illustrate the efficiency of the algorithm. (12 refs.)

The effect of some additives on electroless copper deposition ..See Entry 73007

81.40C Solid solution hardening, precipitation hardening, dispersion hardening

73098 Modification of the spinodal hardening in a Cu-9 wt.% Ni-6 wt.% Sn alloy by 0.1 wt.% silicon or aluminium addition. Ja'Afar Hadi Abboud, E.S.Dwarakadasa (School of Production Engng. & Metall., Univ. of Technol., Baghdad, Iraq).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.233-5 (May 1983).
An attempt was made to study the influence of adding a small amount of a quaternary element to a high strength Cu-Ni-Sn alloy on the nature of thermal hardening that occurs due to a spinodal decomposition process. A positive trend was observed in terms of the stabilisation of the precipitate structure and absence of softening on long ageing. (4 refs.)

73099 Features of heat treatment of sintered type M5F5 fast-cutting steels. G.G.Mukhin, V.A.Korotkova, V.A.Borisova.
Izv. VUZ Mashinostr. (USSR), no.3, p.148-51 (1983). In Russian.
Examines changes in the phase composition of type M5F5 sintered fast-cutting steels, during hardening and tempering. Using metallographic, X-ray and carbide methods of analysis, changes in the grain dimensions, and in the amount of the residual austenite and carbides have been studied. It was found that the primary type MC and M_6C carbides in sintered steels differ from the corresponding carbides of cast steel. It was also established that the small-grain austenite structure in sintered steels is preserved right up to the start of partial melting; for this reason, the main parameter to choose for optimisation should be hardness and not grain number. (6 refs.) *Z.F.V.*

73100 Strengthening of polyphase Si_3N_4 materials through oxidation. F.F.Lange, B.I.Davis, M.G.Metcalf (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA).
J. Mater. Sci. (GB), vol.18, no.5, p.1497-505 (May 1983).
Specimens of various polyphase Si_3N_4 materials fabricated in the Si-Mg-O-N system, and a commercial Si_3N_4 material were subjected to oxidation treatments prior to flexural strength determinations at 1400°C. It was demonstrated that a pre-oxidation treatment could significantly improve the high-temperature strength. The compositional change induced by oxidation which can decrease the volume fraction of the viscous phase present in these materials at high temperatures is believed to be responsible for the observed strengthening. (15 refs.)

73101 Effect of preceding heat treatments on the process of quench ageing in Fe-N alloys. M.Ichimura, M.Imabayashi.
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.113-19 (1982). In Japanese.
The authors examine the influences of quenching temperatures (800°C, 580°C, 400°C), a reversion treatment (250°C) and pre-ageing treatments (300°C, 200°C, 50°C) on a process of metastable nitride precipitation at 100°C. A precipitation of nitride from a supersaturated solid solution of α Fe is studied by an internal friction method. The precipitation process at 100°C is practically unaffected by the changes in quenching temperature and by the reversion treatment. On the other hand, the precipitation of nitride is accelerated remarkably by the pre-ageing treatments and the rate of acceleration increased with decreasing the pre-ageing temperature. (14 refs.)

73102 Effect of precipitates formed during pre-ageing on the process of quench ageing in Fe-N alloy. M.Ichimura, M.Imabayashi.
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.121-6 (1982). In Japanese.
The authors obtained the ageing temperature dependence of the rate of metastable nitride precipitation and the apparent activation energy for precipitation of metastable nitride at 50 to 180°C after pre-ageing at 50°C, 200°C and 300°C. The reason for the effect of precipitates formed by pre-ageing on the precipitation process of metastable nitride was discussed. Except for ageing at higher temperature than 150°C, the precipitation process of metastable nitride was accelerated by pre-ageing and the rate of acceleration was increased with falling of pre-ageing or ageing temperature. (7 refs.)

73103 Hardenability of a high-purity 0.3% Mo eutectoid steel. H.I.Malik (Coll. of Engng. & Petroleum, Univ. of Kuwait, Safat, Kuwait).
Arch. Eisenhuettenwes. (Germany), vol.54, no.3, p.123-4 (March 1983).
The hardenability in 0.3% Mo and 0% Mo steels of eutectoid compositions is determined using quantitative standard methods. There is a slight effect on the Ae_1 temperature, but an increase of the incubation period and the completion of austenite decomposition to pearlite by the addition of 0.3% Mo. There is evidence from Jominy end quench tests that the addition of molybdenum increases the hardenability of steel. (3 refs.)

73104 Strain hardening representation for implicit quasistatic elasto-viscoplastic algorithms. J.M.M.C.Marques (Dept. of Civil Engng., Univ. of Oporto, Oporto, Portugal), D.R.J.Owen.
Comput. & Struct. (GB), vol.17, no.2, p.301-4 (1983).
Time integration processes for the solution of elasto-viscoplastic problems are briefly reviewed. For materials that strain harden, additional terms, which arise from the variation in yield level occurring during a time increment, are included in the expression of the viscoplastic strain rate. The influence of these additional terms is discussed and illustrated by the solution of numerical examples. (6 refs.)

73105 Influence of V and Zr on the rolling texture, recrystallization, and anisotropy of the Young modulus of Ti-V and Ti-Zr alloys. I.G.Zakharchenko, V.V.Nemoshkalenko, V.S.Kshnyakin (K.D. Ushinski Pedagogical Inst., Odessa, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.533-7 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The pole figure method was used to study the formation of the cold rolling texture and changes in the preferential orientation resulting from heat treatment of various Ti-V and Ti-Zr alloys. An estimate was obtained of the anisotropy of the Young modulus. Cold rolling produced a one-component texture, but when the concentration of Zr was in excess of 45%, the texture had two components. Refinement of the texture and an increase in the anisotropy of the Young modulus as a result of annealing were attributed to active polygonization processes. (6 refs.) *A.T.*

73106 Effect of zinc content on the annealing behaviour of deformed alpha-brasses. T.H.Youssef (Metal Phys. Unit., Nat. Res. Centre, Cairo, Egypt), M.A.Kenawy, F.A.Saadalah, M.B.Zikry.
Fizika (Yugoslavia), vol.15, no.1, p.1-9 (Jan.-March 1983).
Hardness measurements, metallographic observations, as well as X-ray diffraction patterns were used to study the annealing of deformed four alpha-brasses of zinc content 3.5, 8.8, 19.4 and 26.8 weight percent. The relaxation spectrum for each alloy was characterized by the presence of three annealing stages. The first one was attributed to the annealing out of vacancies and relative free dislocations. The second annealing stage, observed at higher annealing temperature, was attributed to recrystallization mechanism which takes place by self-diffusion. At much higher temperatures, grain growth mechanism was responsible for the third annealing stage. Increasing zinc content was found to help the annealing mechanisms, as it increases the rate of vacancy diffusion in the matrix, moreover it facilitates slip reactions. This increase takes place in two rates, high rate in alloys of low zinc content, and relative lower rate in alloys of high zinc content. (17 refs.)

73107 Effect of rollers on surface roughness anisotropy of thin-sheet steel. M.F.Sukhov, A.A.Zyuzin, A.M.Kozlov, E.I.Bulatnikov.
Izv. VUZ Mashinostr. (USSR), no.3, p.122-5 (1983). In Russian.
Measurements show that side roughness of working rollers of mills for cold rolling of steel has a dominant effect on the anisotropy of the surface roughness of the steel. The intersecting surface microroughness of strips of electrotechnical steel, with the irregularities inclined at 45 degrees to the rolling direction, exhibits a near-isotropic distribution of the roughness parameters, and has better adhesiveness with an electrically-insulating coating. Measures for improving the surface microroughness of cold rolled steel strips are discussed. (no refs.) *Z.F.V.*

73108 Numerical determination of the parameters of Krupkowski's function for a torsion test taking into consideration the strain hardening ranges. A.Grabianowski (Inst. for Metal Res., Polish Acad. of Sci., Krakow, Poland), J.Kloch.
J. Mater. Sci. (GB), vol.18, no.5, p.1323-30 (May 1983).
A method has been proposed (see A. Krupkowski, Bull. Acad. Sci. Ser. Sci. Tech., vol.17, p.67, 1969) for determining the parameters of a function describing the strain hardening curve for a torsion test taking into consideration the strain hardening ranges. Certain measures for the approximation quantity have been defined by means of which it is possible to formulate the criterion of the occurrence of these ranges. Experimental verification of the method was carried out using nickel of 99.95% purity. Test pieces of a circular cross-section were subjected to a torsion test at ambient temperature without taking into consideration the strain hardening rate. (9 refs.)

73109 A study on the effects of intermediate annealing in 3% single oriented silicon steel. Bong Hee Hahn (Coll. of Engng., Seoul Nat. Univ., Seoul, Korea), Hee Kyong Moon.
J. Korean Inst. Met., vol.21, no.1, p.7-13 (Jan. 1983). In Korean.
The effects of the intermediate annealing in the two stage cold rolling of 3% Si steel on the secondary recrystallization have been studied. When the conditions are excessive (1000°C for longer than 10 min, 1100°C for longer than 5 min), the (110) [001] component is so dominating that it subsequently prevails in the primary recrystallized grains. Hence the grains are small after high temperature annealing. When the conditions are insufficient (700°C for shorter than 5 min, 800°C for shorter than 2 min), the rolling texture (112) [110] considerably remains. After rolling this component rotates into (111) [110] which remains very strong in primary grains. Hence the secondary recrystallization is incomplete. In compromising conditions the relevant proportion of (110) and (111) in the primary grains is obtained, which results in good secondary recrystallization behavior. (7 refs.)

73110 A study on the development of oriented 3% silicon steel. D.Y.Won, H.K.Lee, H.B.Im, J.T.Kim, K.Lee, C.W.Kim.
J. Korean Inst. Met., vol.21, no.1, p.14-18 (Jan. 1983). In Korean.
A study on the development of boron 3% silicon-iron containing 0.03/0.04 C, 0.07/0.08 Mn and boron (30 ppm add) was carried out. Samples prepared by two stage cold reduction method developed complete secondary recrystallization, while samples prepared by one stage cold reduction method showed incomplete secondary recrystallization and poor magnetic properties. The magnetic properties also varied with normalizing temperature, and the sample prepared by normalizing at 950°C showed the best magnetic properties. The induction with a magnetizing force of 800 A/m was 1.86 tesla. (7 refs.)

73111 The texture in diffusion-grown layers of trialuminides $MeAl_2$(Me=Ti, V, Ta, Nb, Zr, Hf) and VNi_3. J.Maas, G.Bastin, F.van Loo, R.Metselaar (Lab. for Phys. Chem., Eindhoven Univ. of Technol., Eindhoven, Netherlands).
Z. Metallkd. (Germany), vol.74, no.5, p.294-9 (May 1983).
A series of intermetallic compounds was prepared with the $TiAl_3$ structure or related structures. The layers of the tri-aluminides formed in diffusion couples do not grow according to the parabolic law. Most of the diffusion-grown layers show a weak texture. Generally, a fibre texture parallel to the direction of diffusion, consisting of two components has been found together or separately in the same layer. In $NbAl_3$, VAl_3 and $TaAl_3$ the nature of the texture was a ⟨110⟩ and a ⟨100⟩ fibre texture. In $TiAl_3$ layers a ⟨100⟩ fibre texture has been found together with an exceptional component, a [001]-fibre texture, probably related to the formation of a superstructure In $HfAl_3$-layers grown on a Hf substrate with a sheet texture, the texture in the $HfAl_3$-layer was not rotationally symmetric around the direction of diffusion, but a related sheet texture developed. In the case of textureless Hf substrates the $HfAl_3$ layers exhibit a [001]-fan texture. In $VN1_3$- layers no texture was produced. (28 refs.)

81.40G Other heat and thermomechanical treatments

73112 The sintering of creep-induced cavities in a low-alloy ferritic steel (1Cr1Mo0.75V). R.A.Stevens, P.E.J.Flewitt (Sci. Services Dept., CEGB, Gravesend, England).
Metall. Trans. A (USA), vol.14A, no.4, p.679-86 (April 1983).
Sintering heat treatments at temperatures in the range of 1173 to 1273K have been undertaken in an atmospheric pressure of argon gas to remove grain boundary cavities within a 1Cr1Mo0.75V ferritic steel (Durehete 1055) following creep rupture after service operation at 838K. High sensitivity density measurements and optical metallography have been used to monitor the progressive sintering of cavities. The results are discussed in relation to existing models which describe the sintering of cavities by grain boundary diffusion. (25 refs.)

73113 Behaviour of titanium alloy Ti-6% Al-4% V in the range of hot heating.. J.G.Malcor, F.Montheillet (Ecole des Mines de Paris, Centre de Mises en Forme des Materiaux, Valbonne, France).
Mem. & Etud. Sci. Rev. Metall. (France), vol.80, no.2, p.89-101 (Feb. 1983). In French.
The results of hot torsion tests, between 800 and 1200°C and in the velocity range 5.10^{-3} to 5 s^{-1}, performed on two initial structures, either equiaxial or acicular, are presented. The behaviour rule of TA 6 V in the range of hot forging is determined. (14 refs.)

73114 The effect of the atmosphere of heat-treatment on the cobalt ions in the cobalt aluminumoxides with the spinel structure. T.Yao, H.Jinno (Dept. of Industrial Chem., Kyoto Univ., Kyoto-shi, Japan).
Yogyo-Kyokai-Shi (Japan), vol.91, no.3, p.131-6 (1983). In Japanese.
The effect of the atmosphere of heat-treatment on the valence and the coordination state of the cobalt ions were investigated. Cobalt carbonate and α-alumina were mixed in the equimolar ratio, and the mixture was heat-treated at 1400°C or 1300°C under various partial pressure of oxygen (P_{O2}) from 2.1×10^{-1} atm to 1.7×10^{-7} atm for the heat-treatment at 1400°C, and from 2.1×10^{-1} atm to 1.1×10^{-8} atm at 1300°C. The lattice constants and the photoacoustic spectra (PAS) of the samples were measured. The lattice constants were scarcely changed with temperature and oxygen partial pressure of the heat-treatment (Table 1). In the PAS of the samples heat-treated in low P_{O2} region, only the peak corresponding to the $^4A_2(F) \rightarrow {}^4T_1(P)$ transition of Co^{2+} ions in the tetrahedral sites was observed. Onthe samples heat-teated in high P_{O2} region, however, additional peaks were observed, corresponding to the $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transition of Co^{2+} ions in the octahedral sites and also to the $^1A_{1g}(D) \rightarrow {}^1T_{2g}(D)$ and $^1A_{1g}(D) \rightarrow {}^1T_{1g}(D)$ transitions of Co^{3+} ions in the octahedral sites. (33 refs.)

73115 Control of microstructures of (α+β)-titanium alloys. M.Peters (Inst. fur Werkstoffe, Ruhr-Univ. Bochum, Bochum, Germany).
Z. Metallkd. (Germany), vol.74, no.5, p.274-82 (May 1983).
Commercial (α+β)-titanium alloys are generally classified into three microstructural groups according to the geometrical arrangement of the two phases α and β: lamellar, equiaxed, and a mixture of both which is therefore called bi-modal. Lamellar structures are readily controlled by heat treatments. In contrast equiaxed and bi-modal structures require additional deformation procedures because they are established by recrystallization. The parameters which control their homogeneity are the deformation and recrystallization conditions as well as the starting structure before deformation. The finest equiaxed microstructures achieved had α grain sizes of about 2 μm. (36 refs.)

73116 Transmission electron microscopy of an annealed and nitrided Fe-600 wt.ppm Ti alloy. M.Foldeaki, M.Rapp, H.Kronmuller (Max-Planck-Inst. fur Metallforschung, Inst. fur Phys., Stuttgart, Germany).
Z. Metallkd. (Germany), vol.74, no.5, p.283-8 (May 1983).
Systematic investigations of the microstructure of a Fe-600 wt.ppm Ti alloy have been carried out with regard to different annealing and nitriding treatments. The structure controlling factor of both treatments is the annealing temperature which influences the precipitation and nucleation behaviour of Ti itself (annealing) as well as the formation of TiN (nitriding). (16 refs.)

73117 On γ and γ′ phases composition in Ni-base superalloys after high-temperature exposure. M.Magrini, B.Badan, E.Ramous (Istituto di Chimica Industriale, Univ. di Padova, Padova, Italy).
Z. Metallkd. (Germany), vol.74, no.5, p.314-16 (May 1983).
The chemistry and volume fraction of γ′ phase in IN-100, UD-520 and UD-710 superalloys after high-temperature exposure in service have been examined. In the three alloys after exposure the γ composition remains nearly constant and the concentration of (Al+Ti) in γ′ phase increases, approaching the theoretical value of 25%. The results suggest that Cr, Mo and W aim to occupy different sites in the γ′ lattice in the three examined alloys. (13 refs.)

73118 Comparison of the quench rates attained in gas atomized powders and melt-spun ribbons of Co and Ni base superalloys: influence on resulting microstructures. F.Duflos, J.F.Stohr (ONERA, Chatillon, France).
Rapidly Solidified Amorphous and Crystalline Alloys. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.167-71
The cooling rates during solidification of gas atomized Stellite 6 (S6) powders range from 10^3 K/s to 10^6 K/s for 400 μm diameter powder particles respectively. The microstructures vary from equiaxed type in the coarser particles to fully dendritic, cellular and microcrystalline in the finer particles. In the case of melt spun ribbons, the variations in freezing rate along a cross section of the ribbon produce a change in the microstructure from microcrystalline at cooling rates greater than 10^7 K/s to cellular and finally dendritic at rates on the order of 10^6 K/s. 81.40J Elasticity and anelasticity

(see also 62.20D Elastic constants, 62.40 Anelasticity, internal friction, and mechanical resonances)

73119 The calculation of a composite cylindrical shell of steel and concrete. Wang Zhen-ming (Inst. of Mech., Acad. of Sinica, Beijing, China).
Acta Mech. Solida Sin. (China), no.3, p.409-20 (1981). In Chinese.
A composite cylindrical shell of steel and concrete for a large floating cover oil tank is used to investigate the stress analysis problem of a bilayer cylindrical shell under the action of liquid pressure, temperature difference and the contraction of concrete. An example of calculation of an oil tank of 2×10^5 M^3 is given to illustrate the advantages of this composite structure. (6 refs.)

73120 A new relationship of DC conductivity with loss modulus in PET. N.Chand (Polymer Sci. & Engng. Group, Nat. Chem. Lab., Pune, India).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.183-4 (May 1983).
An attempt has been made to correlate the DC conductivity (σ) with the dynamic loss modulus (E'') of polyethylene terephthalate (PET). An equation is derived of the form $\log(\sigma/RT) = -4.6 \log(E''/W) + C$ where R and C are constants, T is the temperature and W is the frequency. (5 refs.)

73121 The stiffness and modulus of elasticity of grey cast irons. L.Haenny, G.Zambelli (Dept. des Materiaux, Ecole Polytech. Federale de Lausanne, Lausanne, Switzerland).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.239-42 (May 1983).
It is difficult to apply the concept of the modulus of elasticity in the case of a grey cast iron. Three parameters are defined to overcome this problem and it is shown that whatever the prestrain applied, the stress/strain curve of a work hardened grey cast iron remains similar and is only modified by a multiplying factor. (4 refs.)

73122 Cyclic stress relaxation of polycrystalline metals at elevated temperature. G.J.Weng (Dept. of Mech. & Materials Sci., Rutgers Univ., New Brunswick, NJ, USA).
Int. J. Solids & Struct. (GB), vol.19, no.6, p.541-51 (1983).
The influence of a relatively small, superimposed alternating strain on the relaxation behavior of structural metals is examined from the micromechanics standpoint, taking into account the nature of crystallographic slip in the grain and grain interactions. The initial mean strain is allowed to be sufficiently large to include both elastic and plastic components. To facilitate the evaluation of this instantly relaxed stress state Hill's self-consistent relation for an elastoplastic polycrystal is modified from its incremental to a total form for a monotonic straining process. The self-consistent relation previously derived for static relaxation of an elastic-creep medium is also extended to the dynamic condition, and for an elastic-plastic-creep medium. Together with a set of unified constitutive equations of slip systems, these self-consistent relations are used to determine the cyclic relaxation behavior of a 0.16% carbon steel at various strain amplitudes. The results are seen to be in close agreement with the experimental data, both showing that the relaxation mean stress could be greatly facilitated by the presence of a small strain amplitude. (16 refs.)

73123 Internal friction due to hysteretic dislocation motion in solid solution crystals. O.Boser (Philips Labs., Briarcliff Manor, NY, USA).
J. Appl. Phys. (USA), vol.54, no.5, p.2338-43 (May 1983).
In analogy to Rayleigh's law in magnetism a Rayleigh law of plastic deformation is defined to explain the amplitude dependent internal friction and the modulus defect in materials with high solute concentrations. The forces opposing dislocation motion in a solid solution crystal with high solute concentrations are described with the help of random functions. Using this statistical treatment it is possible to calculate the parameters of Rayleigh's law of plastic deformation and explain quantitatively the amplitude and concentration dependence of the internal friction and modulus defect in alpha brass. (17 refs.)

73124 Study on physical properties of cement paste and mortar at early age by ultrasonic pulse method. S.Kakuta (Akashi Technol. Coll., Akashi, Japan), T.Akashi.
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.353, p.175-81 (Feb. 1983). In Japanese.
Describes the analytical results of the physical properties of cement paste and mortar aged at 20±2°C up to 3 hours or 24 hours. The ultrasonic method was applied to investigate the longitudinal and the transverse pulse propagation properties. The dynamic modulus of elasticity, the dynamic modulus of viscosity and the relaxation time of cement paste and mortar were calculated from the pulse velocity, the frequency and the attenuation constant, respectively, and they were found to be frequency dependent in this time period. The dynamic modulus of elasticity of cement paste changed from 10^7 to 10^9dyn/cm^2 depending upon the water cement ratio and the elapsed time, and the dynamic modulus of viscosity from 10 to 10^5 dyn.sec/cm^2, until the age of 3 hours. The dynamic shear modulus and the dynamic bulk modulus were calculated by the longitudinal and the transverse pulse velocities and the density of specimens. (7 refs.)

73125 Characteristics of expansive concrete under bi-axial restraint. K.Okada, M.Ohta (Faculty of Engng., Kyoto Univ., Kyoto, Japan), T.Nagafuchi, A.Yata, S.Tamai.
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.353, p.182-7 (Feb. 1983). In Japanese.
The expansion characteristics of expansive concrete are greatly dependent upon the restraint condition of concrete itself. The restrained expansive strains of main (longitudinal) and lateral reinforcing steels embedded in expansive concrete as well as the relations between them were investigated experimentally and theoretically. Under biaxial restraint, the chemical prestressing in one direction due to the restraining steel reduces the expansion in another direction. By considering the poisson's effects, an equation was proposed. (3 refs.)

73126 Internal friction of palladium boron alloys. H.Brodowsky, J.Fleischhauer, M.Kayashima (Inst. fur Phys. Chem., Univ. Kiel, Kiel, Germany).
Scr. Metall. (USA), vol.17, no.4, p.541-3 (April 1983).
Internal friction peaks were observed for Pd-B_1 samples with 0.3 to 2%B. The temperature at which the damping factor Q^{-1} had its maximum varied between 200 and 217K for frequencies between 0.25 and 11 cps. (10 refs.)

73127 Effect of some force factors on the rigidity characteristics of a magnesium-boron fiber composite material. A.F.Voitenko, V.K.Samarin, A.I.Gordienko (Inst. of Materials Sci., Acad. of Sci., Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.715-17 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.39-42 (Sept. 1982). [received: March 1983]
Values of moduli of rigidity of a fiber-reinforced composite calculated in accordance with the mixture rules surpass those determined by experiment. In order to allow correctly for rigidity, in design calculations it is necessary to employ values found in experiments involving given modes of loading and load levels. In assessments of the reliability and useful life of structural elements made of reinforced composite materials allowance must be made for the fact that cyclic loading alters the rigidity of such materials. (7 refs.)

73128 The shape of stress relaxation curves and the mechanical equation of state in molybdenum. K.Tanoue (Dept. of Metal Processing Engng., Kyushu Inst. of Technol., Kitakyushu, Japan), O.Nakano, H.Matsuda.
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.205-15 (April 1983).
It has been demonstrated that a family of $\log \dot{\epsilon}$ vs. $\log \sigma$ curves, obtained from stress relaxation tests after monotonic loading, can be superposed on one another by translation (scaling) along a particular direction and that the locus of the translation is linear. The effects of (1) cyclic loading, (2) imposed strain rates, (3) impurities and (4) grain sizes on the shape of $\log \dot{\epsilon}$ vs. $\log \sigma$ curves and the scaling parameter, m have been studied. Stress relaxation curves are concave, and the linear relationship of the locus holds for scaling except for the stress relaxation after fatigue tests and that of single crystals. Measured m values are dependent on impurities and temperature, and independent of other factors. The physical meaning of the scaling locus is discussed referring to the experimental results. The locus of translation is explained by the relation between the preexponential terms $\dot{\epsilon}_0$ and the maximum internal stress $\sigma_1{}^0$. The mechanical equation of state, $f(\dot{\epsilon},\sigma,(\dot{\epsilon}_0,\sigma_1{}^0),T)=0$ is shown to be valid for an arbitrary value of $(\dot{\epsilon}, \sigma, T)$, provided the scaling is possible. (17 refs.)

73129 On Young's modulus of ferritic cast iron. D.Lohe, O.Vohringer, E.Macherauch (Inst. fur Werkstoffkunde I, Univ. Karlsruhe, Karlsruhe, Germany).
Z. Metallkd. (Germany), vol.74, no.5, p.265-73 (May 1983). In German.
The influence of nodular, vermicular and flake graphite shapes on Young's modulus of ferritic cast iron with similar chemical composition has been investigated by a resonance method. With respect to their spacial shapes the graphite particles can basically be classified by spheres, plates and needles and can quantitatively be described by a shape factor η. η extends from $\sim$1.5 in the case of nodular cast iron to $\sim$40 in the case of coarse flake graphite cast iron. Young's moduli of the cast irons investigated with increasing η values decrease up to a factor two. Smaller Young's moduli of cast irons in relation to graphite-free basic alloys are caused by increasing strain contributions of the graphite particles with increasing η values. Measured Young's moduli of cast irons in different graphite shapes are in good agreement with theoretical calculations carried out with two-phase materials especially with regard to the second phases as spheres, plates and needles. 73130 Bending strength of silicon nitride at 1250°C under static and cyclic bending load. H.Heigl (Inst. fur Werkstoffkunde, Hochschule der Bundeswehr, Munchen, Germany), K.Heckel.
CFI-Ceram. Forum Int. Ber. Dtsch. Keram. Ges. (Germany), vol.60, no.2-3, p.69-73 (April 1983). In German, English.
The bending strength of reaction bonded silicon nitride at 1250°C is higher than the bending strength at room temperature. A long-time thermal treatment of oxidized specimens has no appreciable influence on the static bending strength at 1250°C. No fatigue failure was observed at one-step fatigue tests up to 20 million cycles of loading. If an oxidized part loaded mainly with bending stresses does not fail at room temperature, it can be expected that it will also stand the load at 1250°C. (4 refs.)

73131 Effect of structural defects on the sorption volume and strength of glass reinforced plastics. V.G.Makarov, S.M.Perlin, A.A.Antonov (Kubyshevskii Polytech. Inst., Kubyshevskii, USSR).
Vysokomol. Soedin. Ser. B (USSR), vol.25, no.3, p.182-6 (1983). In Russian.
The effects of the porosity of glass-reinforced plastics on their strength and absorption properties are reported for high-tensile, glass-fibre filled epoxides. The results for samples with glass fibres from 10-20 micron diameter show water absorption capacities at 45-100% humidity, rupture stress and macro- and micro-defect concentrations as functions of porosity in the range up to 10% porosity. It is shown that strength is enhanced by reducing the porosity and is higher for a uniform pore structure, which reduces the probability of macro-defects. Moisture absorption of short duration leads to a reversible loss of strength, but long-term (over 1000h) absorption to a permanent loss. The absorption effect can be avoided by sealing the surface with a thermoplastic or by creating a diffusion barrier at the surface. (7 refs.) *C.J.S.*

73132 Effect of plasticisation on the durability of orientated polymers. Yu.M.Ivanov.
Vysokomol. Soedin. Ser. B (USSR), vol.25, no.3, p.189-93 (1983). In Russian.
Moisture-bonded (wood) cellulose with up to 30% plasticiser (bonded moisture) and polyamide fibres are selected as examples of highly plasticised, fibrous polymers for which literature, experimental data are available for the long-term (typically up to 5 years) mechanical properties. It is shown that the variations in durability caused by molecular plasticisation of orientated polymers can be accounted for using a structurally sensitive coefficient. An expression is obtained for the coefficient for cellulose which involves time, plasticiser concentration, temperature, stress and the rupture activation energy. (18 refs.) *C.J.S.*

73133 Investigation of stresses created by electrically insulating coatings in electrical steel sheet with a ribbed texture. L.M.Sheiko, O.N.Ivanchenko, L.S.Chervonev, F.D.Miroshnichenko (Zaporozhye State Pedagogical Inst., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.201-4 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1427-30 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
As a result of application of insulating coatings, electrical steel with a ribbed texture may give rise to not only isotropic extension in the plane of the sheet, but also to the more general case of the plane stress state when the principal stresses $\sigma_{ii}$are not equal to one another. The factors causing the ratio of the principal stresses $k_0=\sigma_{22}/\sigma_{11}$ of the tensor σ_{ij} and its individual components σ_{ii} to assume unequal values for different types of coating probably stem from differences in the way in which the coatings are obtained. Among such differences are: conditions of formation of the ceramic layers of the coating; composition of the solutions employed; particular admixtures in the initial materials. (10 refs.)

73134 Strain mechanisms in grey cast iron. L.Haenny, G.Zambelli (Ecole Polytech. Federale, Dept. des Materiaux, Lausanne, Switzerland).
Eng. Fract. Mech. (GB), vol.18, no.2, p.377-87 (1983).
Grey cast iron exhibits a continuous stress-strain curve on which elastic and plastic strains cannot be identified. Tensile straining is analysed in the case of a grey cast iron solidified by continuous casting. It is demonstrated that the main damaging processes are directly related to strain components which can be macroscopically identified. The amount of microcracking is evaluated by the decrease in elastic stiffness. On complete unloading, a small increase in the elastic stiffness is recorded; however, the initial value is not recovered. Deformation due to localized plastic strains is evaluated by recording the tangent modulus. For stresses inducing negligible creep strains the tangent modulus decreases linearly for increased applied stress. Under low stress amplitude, however, an elastic range is clearly observed. (12 refs.)

73135 Analysis of the characteristics of lumped deformation of heterophase crystalline materials. M.N.Pankova, V.A.Solov'ev, S.G.Zaichenko (Inst. of Metallography & Phys. of Metals, Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.576-82 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A theoretical study is made of the probability of excitation of secondary shear processes in the field of stresses of primary lumped shear stopped by a layer of a reinforcing phase. The thicknesses of the obstacles necessary to prevent shear are found, i.e. those necessary to suppress macroscopic deformation while retaining the local compliance of a material. Specific calculations are made of the probabilities of the processes occurring in the course of martensitic transformations and resulting in the formation of lightning-shaped groups and branches in martensite grains in real steels. (9 refs.) *A.T.*

73136 Relationship between the coefficients of normal anisotropy in the plastic behaviour of sheet metals. J.D.Bressan, J.A.Williams (Dept. of Engng., Univ. of Cambridge, Cambridge, England).
Int. J. Eng. Sci. (GB), vol.21, no.7, p.847-9 (1983).
Hill (see Math. Proc. Camb. Phil. Soc., vol.85, p.179, 1979) has proposed a refinement of his classical yield function to account for the discrepancies observed between the material stress-strain curve obtained from biaxial stretching experiments and that predicted on the basis of data from uniaxial tension tests. These discrepancies are greatest when the coefficient of normal anistropy, R, is less than unity. For plane stress conditions, with principal in-plane stresses σ_1 and σ_2 the new yield function can be written as $2(1+R)Y^m=(1+R)|\sigma_1-\sigma_2|^m+|\sigma_1+\sigma_2|^m$ where Y is the uniaxial yield stress in tension. m is a new material parameter introduced to give the yield function a more general character and to accommodate specifically the anisotropic plastic behaviour of materials for which $R<1$ and for which therefore normal anisotropy is described by two parameters R and m. (6 refs.)

73137 Hydrophilic polymeric membranes obtained by radiation cast-copolymerization of ethyl acrylate with various monomers. M.Kumakura, I.Kaetsu (Takasaki Radiation Chem. Res. Establ., JAERI, Takasaki, Gunma, Japan).
J. Mater. Sci. (GB), vol.18, no.5, p.1335-40 (May 1983).
Hydrophilic polymeric membranes were prepared by radiation cast-copolymerization of ethyl acrylate with various diacrylates and dimethacrylates. The hydration and mechanical properties of the copolymers were studied as a function of copolymerization composition. The degree of hydration, tensile strength, tear strength, elongation at break, and Young's modulus increased with decreasing concentration of the ethyl acrylate component. In a certain copolymerization composition, the hydrophilic polymeric membranes which resemble the mechanical property of the biomedical materials were obtained. (8 refs.)

73138 Bending properties of creased zones of paperboard related to interlaminar defects. L.Carlsson, A.De Ruvo, C.Fellers (Dept. of Paper Technol., Swedish Forest Products Res. Lab., Stockholm, Sweden).
J. Mater. Sci. (GB), vol.18, no.5, p.1365-73 (May 1983).
A parallel beam model is presented for the bending behaviour of locally delaminated zones (creases zones) of paperboard. It is shown that the bending moment and the force levels are strongly dependent on the geometry and elastic properties of the creased zone. A favourable condition for low crease stiffness is a large number of long interlaminar failures. Experimental measurements of the crease stiffness and maximum bending moment for paperboards with implanted defects of various lengths and numbers were in reasonably good agreement with the crease stiffness predicted by the parallel beam model. (7 refs.)

73139 Effect of vacuum-treatment on mechanical properties of W-Ni-Fe heavy alloy. H.K.Yoon, S.H.Lee, S.-J.L.Kang, D.N.Yoon (Dept. of Materials Sci. & Engng., Korea Advanced Inst. of Sci. & Technol., Seoul, Korea).
J. Mater. Sci. (GB), vol.18, no.5, p.1374-80 (May 1983).
The effect of heat treatment in vacuum and hydrogen on the ductility and UTS of the sintered 96W-2.8Ni-1.2Fe (by wt%) heavy alloy has been studied. The elongation of the as-sintered alloy is about 8%, but after a few minutes of heat treatment in vacuum at 800°C it increases markedly to about 19%. When the sintered specimen is heat-treated in vacuum at 600°C, the elongation increases rapidly with time, reaching 20% after about 10 min. The values of UTS also increase after vacuum treatment. Heat treatment in hydrogen, however, shows no change in mechanical properties from the as-sintered state. The effect of vacuum treatment is thus attributed to the removal of hydrogen embrittlement. Based on the hydrogen diffusion model, a practical guideline is suggested for determining the optimum vacuum treatment conditions. The scanning electron micrographs of the fracture surfaces show that hydrogen weakens mainly the interface between tungsten grains and matrix. (14 refs.)

73140 The effects of extensional creep and creep recovery on the dynamic properties of an unfilled and filled crosslinked polyester resin. D.Katz, Y.Smooha (Dept. of Materials Engng., Technion Israel Inst. of Technol., Haifa, Israel).
J. Mater. Sci. (GB), vol.18, no.5, p.1482-90 (May 1983).
Changes in the dynamic properties of unfilled and filled cured polyester resins during extensional creep were measured with the aid of a modified torsion pendulum. Glass beads were used as filler. The decrease in the real shear modulus during creep is attributed mainly to a debonding process. Dewetting-rewetting processes reflected by modulus changes, were discussed on the basis of a theory of Takahashi et al. (1978). Voigt-Kelvin rheological models were used to characterize the modulus and the creep compliance recoveries after load release. (7 refs.)

73141 Straw-reinforced polyester composites. N.M.White, M.P.Ansell (School of Materials Sci., Univ. of Bath, Bath, England).
J. Mater. Sci. (GB), vol.18, no.5, p.1549-56 (May 1983).
Annual crop fibres are rich in cellulose and they are a cheap and rapidly renewable source of fibres with potential for polymer reinforcement. Straw fibres have been incorporated in a polyester resin matrix and the properties of the fibre and composite determined. The fibres have a Young's modulus of approximately 8 GN m^{-2} and an effective density of 5.1 kN m^{-3} when combined with resin. Useful composites can be formulated with an optimum fibre volume fraction of about 0.61, resulting in a flexural stiffness of 7.3 GN m^{-2} and flexural strength of 56 MN m^{-2}. The specific flexural stiffness is about 2.5 times greater than that of polyester resin and about half that of softwoods and GRP. The work of fracture measured in impact is about half that of softwoods. It is envisaged that alternative methods for processing the fibres and the use of a phenolic resin matrix will improve the composite properties further. Straw-based composites are suitable as core material for structural board products. (10 refs.)

73142 Compaction effect on flexural behaviors of fiber reinforced concretes. K.Okada (Faculty of Engng., Kyoto Univ., Kyoto, Japan), T.Mise, M.Mashima, T.Ideguchi.
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.353, p.168-74 (Feb. 1983). In Japanese.
Fiber reinforced concrete contains a large amount of short fibers randomly dispersed into cement concrete and this composite material is superior to normal plain concrete with respect to its flexural strength, impact resistance and ductility. But the consistency of concrete is extremely decreased by adding fibers so that in some cases it becomes difficult to place and mold by the ordinary method. The effects of compaction methods on the strength of fiber reinforced concretes having poor consistency and containing a fairly large amount of fibers were investigated. Conventional steel fibers and

alkali-resistant glass fibers were used. Test specimens (10×10×60 cm) of plain and fiber reinforced concretes were compacted by external vibration with temporary or continuous compressive loading, and were tested in flexure. The test results indicate that the compaction with compressive loading increases the flexural strength of both types of fiber reinforced concretes as well as the extensibility of glass fiber reinforced concrete although the improvement is made within a certain limit of compaction loading. (6 refs.)

73143 Characteristics of microstructure during tensile deformation of superplastic Al-Zn eutectoid alloy. Y.Motohashi, T.Shibata (Dept. of Mech. Engng., Ibaraki Univ., Hitachi, Ibaraki, Japan).
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.49-59 (1982).
Microstructures during plastic deformations were studied by scanning electron microscopy and the plastic-carbon replication technique. Grain boundary sliding (GBS) is a predominant deformation mode in the initial stage of strain ($\varepsilon \lesssim 50\%$). The GBS decreases as the strain increases and the elongation of Zn rich phase along the tensile axis predominates after large strains ($\varepsilon \gtrsim 100\%$). Grain-growth of the Zn rich phase is also observed, while that of Al rich phase is only little. The Al rich phase becomes a spheroidal shape and is surrounded by the Zn rich phases. Therefore, initial equiaxial structure of the alloy has broken after large strains, but the superplastic deformation continues. No evidence of crystallographic slip (CS) in the grains is observed. Both GBS and CS occur in a region in which the alloy deforms at low temperatures (230 to 253K) and high stresses. Large ductility of the Zn rich phase caused by preferential diffusion of Zn is a significant mode of superplastic deformation for this alloy. (10 refs.)

73144 Role of grain boundary segregation in diffusional creep. E.D.Hondros, P.J.Henderson (Div. of Materials Applications, Teddington, England).
Metall. Trans. A (USA), vol.14A, no.4, p.521-30 (April 1983). (Symposium on 'The Role of Trace Elements and Interfaces in Creep Failure', Dallas, TX, USA, 14-18 Feb. 1982).
The high temperature deformation of polycrystalline materials by the stress directed flow of vacancies is now a well established creep mechanism which operates in two temperature regimes: high temperature, or Nabarro-Herring creep, in which lattice diffusion is rate determining, and low temperature, or Coble creep, in which grain boundary diffusion predominates. Multicomponent engineering alloys will normally experience, as part of their processing history or service lives, the segregation enrichment of interfaces such as grain boundaries by species present in solid solution. The authors evaluate the experimental information and to explore the manner in which this segregation affects the principal forms of diffusional creep. Cases of retarded Herring-Nabarro creep are analyzed in terms of the efficacy of grain boundaries as sources and sinks for vacancies: strongly bound segregant atoms at grain boundaries affect the mobility of defects and hence control the operation of vacancy sources. They assess the magnitude of the effect induced by various surface active species on grain boundary diffusivity and consequently on Coble creep; predictions show that in general, small amounts of highly surface active impurities induce a remarkable inhibition of this form of creep. (31 refs.)

73145 Crack and cavity nucleation at interfaces during creep. M.H.Yoo (Oak Ridge Nat. Lab., Oak Ridge, TN, USA), H.Trinkaus.
Metall. Trans. A (USA), vol.14A, no.4, p.547-61 (April 1983). (Symposium on 'The Role of Trace Elements and Interfaces in Creep Failure', Dallas, TX, USA, 14-18 Feb. 1982).
Athermal nucleation of microcracks and thermal nucleation of cavities during creep deformation are reviewed with an emphasis on effects of solute segregation to grain boundaries and cavity surfaces. The magnitude and the duration of stress concentration at a triple grain junction or at a grain boundary inclusion are estimated for transient Coble creep and steady state power-law creep conditions. Stable configurations of wedge-type microcracks are predicted by a Griffith-like crack model. The rate for thermal nucleation of cavities is obtained by the Fokker-Planck equation for vacancy clusters. Cracks and cavities are interdependent, and cavity nucleation occurs continuously throughout the three creep stages. The local stress concentration enhances microcrack and cavity nucleation. The cavity nucleation rate is generally increased as a result of solute segregation to the surfaces and interfaces and/or gas precipitation into cavity volume. This enhanced nucleation is more effective in a system with mobile solutes than with immobile solutes. Immobile solute or trace elements may affect the nucleation rate also by changing the grain boundary diffusivity. Experimental techniques for quantitative analyses of cavity nucleation processes are discussed. (83 refs.)

73146 The effects of segregation on the kinetics of intergranular cavity growth under creep conditions. W.D.Nix, K.S.Yu, J.S.Wang (Dept. of Materials Sci. & Engng., Stanford Univ., Stanford, CA, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.563-70 (April 1983). (Symposium on 'The Role of Trace Elements and Interfaces in Creep Failure', Dallas, TX, USA, 14-18 Feb. 1982).
Intergranular cavity growth under creep conditions is examined with particular reference to the potential effects of segregation on cavity growth. When cavities are present on all of the boundaries in a polycrystalline solid, they are able to grow in an unconstrained manner. Under these conditions the rate of cavity growth may be controlled by grain boundary diffusion (D_{GB}), surface diffusion (D_s), or power law creep, which in turn is controlled by lattice diffusion (D_L). When only isolated boundaries are cavitated, cavity growth is constrained and may be completely limited by creep flow of the surrounding grains. The segregation of solute to the grain boundary and the cavity surface can influence the kinetics of cavity growth in several different ways. The reduction in surface energy associated with segregation can increase the rate of cavity growth when the cavities are crack-like. The effects of segregation on grain boundary and surface diffusion can also influence the rate of cavity growth. A phenomenological relation proposed by Borisov et al. indicates that D_{GB}/D_L decreases with segregation, thus causing grain boundary diffusion controlled cavity growth to be slowed by segregation. In some cases solute additions increase D_L, thus increasing the rate of creep controlled cavity growth. (30 refs.)

73147 The effects of trace impurities on the ductility of a Cr-Mo-V steel at elevated temperatures. S.-H.Chen (Dept. of Materials Sci. & Engng., Univ. of Pennsylvania, PA, USA), T.Takasugi, D.P.Pope.
Metall. Trans. A (USA), vol.14A, no.4, p.571-80 (April 1983). (Symposium on 'The Role of Trace Elements and Interfaces in Creep Failure', Dallas, TX, USA, 14-18 Feb. 1982).
The development of current ideas about impurity effects on the ductility of steels at elevated (creep) temperatures is reviewed and the effects of low temperature intergranular failure (LTIF) studies on these ideas are emphasized, e.g., temper embrittlement studies. The possible mechanisms by which impurities can induce high temperature intergranular failure (HTIF) are then reviewed. It is shown that impurity effects on LTIF and HTIF can be quite different and therefore there need be no correlation between the two phenomenon. Experiments on a bainitic 1 Cr-1.25 Mo-0.25 V steel containing deliberately added Mn, P, Si, and Sn show that these additions can either decrease or have no effect on the extent of HTIF compared with undoped material, depending upon the austenitizing temperature. These results may be due to a possible reduction of segregated grain boundary S due to competition between S and P for available grain boundary sites. (The steels used contain approximately 40 wt p.p.m. residual S.) These results resolve some of the controversies in the literature on the effects of grain boundary impurities on HTIF. (51 refs.)

73148 Residual and trace element effects on the high-temperature creep strength of austenitic stainless steels. R.W.Swindeman, V.K.Sikka, R.L.Klueh (Metals & Ceramics Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.581-93 (April 1983). (Symposium on 'The Role of Trace Elements and Interfaces in Creep Failure', Dallas, TX, USA, 14-18 Feb. 1982).
The heat-to-heat variation in the creep strength and ductility of austenitic stainless steels was reviewed from the viewpoint of residual and trace element effects. Based on data reported in the literature, the creep strength of unstabilized alloys such as types 304 and 316 stainless steel increased with residual element and trace element content. Niobium appeared to be the most potent strengthener. There was no direct evidence that trace elements such as sulfur and phosphorus had a deleterious effect on either strength and ductility. It was assumed that the creep strength and ductility of the unstabilized grades of austenitic stainless steels are controlled by the precipitate characteristics. It follows from this that thermomechanical treatment or residual element additions that affect the precipitate characteristics influence subsequent time dependent mechanical properties. This view is consistent with most of the information in the literature. (53 refs.)

73149 The effect of cerium on high temperature tensile and creep behavior of a superalloy. F.Cosandey (Henry Krumb School of Mines, Columbia Univ., New York, NY, USA), F.Sczerzenie, D.Li, J.K.Tien.
Metall. Trans. A (USA), vol.14A, no.4, p.611-21 (April 1983). (Symposium on 'The Role of Trace Elements and Interfaces in Creep Failure', Dallas, TX, USA, 14-18 Feb. 1982).
The presence of trace impurities such as S and O can cause embrittlement during elevated and high temperature deformation of iron or nickel-base alloys. Various amounts of Ce, ranging from 0 to 0.24 wt. pct, have been added to an iron-nickel base superalloy, Udimet 901, in order to study its role in the refining process of S and O in the melt, hot workability, creep and stress rupture, and microstructure. It is found that Ce addition decreases the O and S content in the melt and improves both the hot workability and creep ductility. An optimum residual Ce content of 30 p.p.m. was found for which ductilities are maximum. Higher residual cerium contents result in deleterious hot embrittlement. SEM as well as TEM/STEM microscopy combined with X-ray EDS spectroscopy were used to determine the inclusion content present in the alloy as the fine spatial microchemistries, especially at grain boundaries. (38 refs.)

73150 Plastic constraint and ductility in tensile notched specimens of amorphous $Pd_{78}Cu_6Si_{16}$. H.Kimura, T.Masumoto (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan).
Metall. Trans. A (USA), vol.14A, no.4, p.709-16 (April 1983).
The plastic constraint factor and tensile deformation mechanics of notch-free and notched specimens of amorphous $Pd_{78}Cu_6Si_{16}$ are studied for a variety of geometries over a temperature range of 77 to 473K. A transition with plate thickness between an antiplane-strain mode and a general yielding mode appears for notch-free and single-edge-notched bulky specimens, showing a set of two intersecting shearing plnes inclined at 51 deg to 54 deg to the tensile axis. For circumferentially-notched round specimens, constrained general yielding occurs beyond a critical notch depth. The plastic constraint factor (L_{exp}) increases with decreasing notch angle; this factor relates to the theoretical factor of slip-line field (L_{cal}) by $L_{exp}=\beta L_{cal}$, where β is constant. The plastic constraint factor attains, at the maximum, 2.4 for deep 0 deg notch; this is nearly equal to the upper limit of Hill's slip-line-field solution, indicating that an amorphous $Pd_{78}Cu_6Si_{16}$ alloy is a 'perfect' ductile material. (26 refs.)

73151 The effect of shear bands on service properties of Ti-6Al-2Sn-4Zr-2Mo-0.1Si forgings. S.L.Semiatin, G.D.Lahoti (Battelle's Columbus Labs., Columbus, OH, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.743-50 (April 1983).
The effect of shear bands on the elevated temperature tensile, creep, and fatigue properties of Ti-6Al-2Sn-4Zr-2Mo-0.1Si (Ti-6242) forgings has been established. Evaluations on forgings containing and not containing shear bands demonstrated that the effect is very small if not negligible in tensile and fatigue loading. For these types of loading, observations were explainable on the basis of the fact that the shear bands are regions of somewhat higher hardness than the remainder of the forging, and, thus, failure tended to nucleate away from the shear bands. In contrast, shear bands had a noticeable effect on stress-rupture properties. The deleterious effects under this type of loading were ascribed to microscopic processes such as enhanced diffusion along shear bands. (23 refs.)

73152 Deformation behavior of blended elemental Ti-6Al-4V compacts. G.Welsch, Y.-T.Lee (Case Inst. of Technol., Case Western Reserve Univ., Cleveland, OH, USA), P.C.Eloff, D.Eylon, F.H.Froes.
Metall. Trans. A (USA), vol.14A, no.4, p.761-9 (April 1983).
A blended elemental Ti-6Al-4V alloy powder, sintered to 99 pct theoretical density, was tested in tension and fatigue and characterized by optical, scanning, and transmission electron microscopy and by X-ray energy dispersive analysis. The microstructure consisted of a combination of equiaxed and low aspect ratio lamellar alpha phase. Two types of pores were observed: macrophores at grain boundaries or triple points, and micropores within alpha regions. Chemical homogeneity was achieved within individual alpha or beta regions with slight compositional fluctuations between different grains. The deformation modes in alpha regions were investigated by transmission electron microscopy on thin foils prepared from tensile and cyclically deformed specimens. Tensile deformation occurred by homogeneous slip on both prismatic and pyramidal alpha slip planes. In cyclic deformation, on the other hand, little slip activity was found except for some heterogeneous slip on the basal plane associated with a relatively large micropore. Micropores of ≤0.5 μm size were found to act as dislocation pinning sites. (26 refs.)

73153 Evaluation of the long-term deformation behaviour of plastic materials. H.Honinger, E.Reichelt.
Plaste & Kautsch. (Germany), vol.30, no.3, p.166-72 (March 1983). In German.
Characteristic values and functions of static long-term deformations are at present assumed in the solution of problems associated with plastic applications. As a result of extensive experimental research, the deformation characteristics of plastics available in the DOR have now been documented. Performance and analysis of creep experiments are also given for PVC, PMMA, ABS, PE, PP, PA, PTFE, EVAC, GUP, PF-SPS, and a number of other polymers. (17 refs.) *A.E.W.*

73154 The tensile strengths of single powders and binary mixtures. S.Y.Chan, N.Pilpel (Dept. of Pharmacy, Univ. of London, London, England), D.C.-H.Cheng.
Powder Technol. (Switzerland), vol.34, no.2, p.173-89 (March-April 1983).
A theory of tensile strength for single powders and binary mixtures has been developed by means of equations incorporating the particle size parameters and the compositions of binary mixtures. New concepts of using 'reduced tensile strength' and choosing a reference state are introduced. These, together with the law of corresponding states, enable the tensile strengths of powders and binary mixtures to be calculated with an accuracy of about ±15%. (21 refs.)

73155 Effect of the type of binding material on the properties of refractory glass-fiber heat-insulation products. V.V.Martynenko, A.N.Gaodu, Z.D.Zhukova, E.I.Zoz, E.V.Degtyareva (Komsomol Kharkov Automobile & Highway Inst., Ukrainian SSR).
Refractories (USA), vol.23, no.9-10, p.491-7 (Sept.-Oct. 1982). Translation of: *Ogneupory (USSR)*, vol.23, no.9, p.39-44 (Sept. 1982). [received: May 1983]
The effect of binders (water glass, silica sol, chromium-aluminophosphate binder, bentonite, and polyvinyl-acetate dispersion) on the basic properties of thermal-insulation glass-fiber refractory articles have been studied. It is shown that the use of polyvinyl acetate as the binder in minimum quantities and density gives the maximum bend strength of glass-fiber thermal-insulation articles, with fairly low shrinkage and thermal conductivity. However, the strength of these articles on heating is minimal. It is established that the use of silica sol as the binder gives minimum shrinkage on heating with fairly low density and thermal conductivity but high strength on heating. However, the distribution of binder in the production of articles is very nonuniform. The best characteristics in the articles are provided by a combined binder consisting of a mixture of silica sol and the polyvinyl-acetate dispersion. (11 refs.)

73156 Mechanical properties of glass-crystal structures based on corundum. I.I.Vishnevskii, N.D.Tal'yanskaya (Sci.-Res. Inst. of Refractories, Ukrainian SSR).
Refractories (USA), vol.23, no.9-10, p.508-14 (Sept.-Oct. 1982). Translation of: *Ogneupory (USSR)*, vol.23, no.9, p.53-8 (Sept. 1982). [received: May 1983]
The dependence of the deformation rate at the established state of creep of glass-crystal corundums on the stress and temperature indicate the essential deviation in the deformation process from the quasiviscous-flow regime. The creep of such structures is determined by the degree of bonding of the crystal phase, the size of the crystals, and the amount and distribution of the glass phase. When the concentration of the glass phase is 3-10%, the specimens of glass-crystal corundum are deformed 10^3-10^4 times more rapidly than the pure crystalline material with similar grain size of corundum. It has been established that the decrease in the deformation after the glass crystal corundums have been annealed (mechanical aftereffect) reaches ~50% of the initial values obtained after creep. (12 refs.)

73157 Structure and properties of permeable fine-fiber materials produced from powders. I.M.Fedorchenko, A.G.Kostornov, O.V.Kirichenko, N.S.Guzhva (Inst. of Materials Sci., Acad. of Sci., Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.718-21 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.42-5 (Sept. 1982). [received: March 1983]
Nickel and Ni-Cr, Ni-Mo, Ni-Cr-Mo, Ni-Fe-Cr, and Ni-Fe alloy FFMs of 10- to 28-μm fiber diameters were obtained, and a study was made of the effect of the key structural characteristics of FFMs on their hydraulic and mechanical properties. (4 refs.)

73158 Change in transverse strain coefficient in a plane stress state. A.A.Ostrovskii (Kiev Engng. Inst. of Food Industry, Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.593-7 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.24-7 (May 1982). [received: May 1983]
The author shows how accounting for the change in the transverse strain coefficient makes it possible to construct stress/strain curves from measurements of just one of the principal strains if the principal stress ratio is known. It also permits experimental determination of the plane stress state created in the working part of broad flat specimens in uniaxial tension. (13 refs.)

73159 Link between stress and strain of initially anisotropic materials with anisotropic strain hardening. V.N.Bastun (Inst. of Mech., Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.615-20 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.42-6 (May 1982). [received: May 1983]
The author considers the method of plotting strain diagrams for initially anisotropic materials with isotropic strain hardening caused by loading following linear trajectories, a method free from limitation applied to the relevant type of resistance to tension and compression. (9 refs.)

73160 Dependence of the strength of materials on temperature and strain rate. V.A.Borisenko, B.D.Kosov, V.P.Krashchenko (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.624-8 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.50-4 (May 1982). [received: May 1983]
The authors present the formulation of a generalising equation correlating the strength of a material, the strain rate, and the thermodynamic parameters (temperature and the spectrum of activation energy of the process of plastic deformation). (12 refs.)

73161 Plastic deformation of a metastable stainless steel at low temperatures. I.A.Shapovalov, V.Ya.Il'ichev (Physicotech. Inst. of Low Temperatures, Acad. of Sci., Kharkov, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.629-35 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.54-9 (May 1982). [received: May 1983]
In plastic deformation at low temperatures of chrome-nickel steel in the as-received condition and also of that heat treated and previously deformed at room temperature, nonuniformity of plastic deformation is observed. The latter is revealed in a break in load on the stress-strain curve and in the formation of a local plastic zone in the sample. The loss of strength of the steel is caused by the occurrence of the martensite transformation. The source of spontaneous origin of martensite may be the cellular dislocation structure in the austenite matrix. (18 refs.)

73162 Deformation of polymeric compounds based on synthetic rubber SKTN in the operating temperature range 203-343K. I.A.Kozlov, N.G.Nikolenko, V.P.Privalko, A.B.Yudin (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.641-3 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.64-6 (May 1982). [received: May 1983]
In order to predict the operational reliability for radioelectronic equipment based on polymeric compounds (PMC) the authors study the temperature dependence of strains occurring in the PMC during operation of the article. Compounds KLT-30 and PK-68 based on low-molecular rubber SKNT used extensively in radioelectronic equipment were selected for study. The study was carried out by means of tensoresistors. (no refs.)

73163 Subsurface plastic deformation in machining 6Al-2Sn-4Zr-2Mo titanium alloy. S.Jeelani (Dept. of Mech. Engng., Tuskegee Inst., Tuskegee, AL, USA), K.Ramakrishnan.
Wear (Switzerland), vol.85, no.1, p.121-30 (15 Feb. 1983).
The effect of cutting speed and tool geometry on the plastic deformation in the surface region of 6242 titanium alloy machined orthogonally under lubricated and unlubricated conditions is determined using the grid technique and metallography. The results show that the magnitude of the plastic deformation in the surface region and the depth of the work-hardened layer increase with an increase in the cutting speed or the tool wear land length. The presence of the lubricant in the cutting region results in a considerable reduction in the subsurface damage. (21 refs.)

(inc. hardness; see also 62.20M Fatigue, brittleness, fracture and cracks)

73164 Strength and fracture toughness of reaction-bonded Si_3N_4. S.C.Danforth, M.R.Richman (Brown Univ., Providence, RI, USA).
Am. Ceram. Soc. Bull. (USA), vol.62, no.4, p.501-4, 516 (April 1983).
Reaction-bonded Si_3N_4 was produced with various microstructures to investigate the effect of α/β ratio on modulus of rupture and fracture toughness. Room-temperature MOR was found to be independent of the α/β ratio of the materials tested, a result of machining-induced flaws rather than inherent microstructural flaws acting as the fracture origins in most cases. Notched-beam fracture toughness was also independent of α/β ratio. The average value was $K_{IC}=2.316\pm0.180$ NM.m$^{-3/2}$, which agrees quite well with the value determined fractographically. (36 refs.)

73165 The load concentration factor and the statistic theory of crack propagation of a unidirectionally fiber-reinforced composite. Fan Fu-qun (South China Polytech. Inst., China).
Acta Mech. Solida Sin. (China), no.3, p.287-95 (1981). In Chinese.
Discusses two principal viewpoints concerning the statistic theory of crack propagation. One is the calculation of stress redistribution due to sequential fiber breaking. By using the model common in shear-lag investigations, both plastic analysis by the deformation theory and elastic analysis are made. The results of the elastic analysis agree with those obtained by J.M. Hedgepeth (1961). Also, studies are made on the development of a crack propagation model. The Gucer-Gurland-Rosen Chain Model is abandoned while a model of a gradually enlarging crack layer is presented. Through a statistic analysis by the method used by A.S. Argon et al. (1974), a formula for calculating the tensile strength of a unidirectionally fiber-reinforced composite is obtained. (12 refs.)

73166 SEM observations of the initiation and propagation of cracks in a short fibre-reinforced thermoplastic composite under stress. N.Sato, T.Kurauchi, S.Sato, O.Kamigaito (Toyota Central Res. & Dev. Labs. Inc., Nagakute-cho, Aichi-gun, Aichi, Japan).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.188-90 (May 1983).
SEM observations were made to study in detail the process of crack initiation and crack propagation in a short fibre-reinforced composite under load. Fractographs indicating the initiation and propagation of the crack were obtained. The short fibre-reinforced composite was made from polyamide 6.6 and 15 vol.% glass fibre. (4 refs.)

73167 Effect of oxidizing environment on the strength of H451, PGX and IG-11 graphites. M.Eto, F.B.Growcock (Dept. of Nuclear Energy, Brookhaven Nat. Lab., Upton, NY, USA).
Carbon (GB), vol.21, no.2, p.135-47 (1983).
The effect of gaseous environment on the compressive and tensile strengths of H451, PGX and IG-11 graphites has been examined. Oxidation was carried out in O_2-, CO_2- and H_2O-containing environments. The stretch losses incurred by H451 and IG-11 graphite did not appear to be affected by the nature of the oxidizing gas. However, the strength loss incurred by PGX graphite appeared to be greater in O_2 than in CO_2 or H_2O. A mechanism consistent with the observed behavior of PGX graphite is proposed: the iron impurity, which is locally distributed in the binder, may be catalytically active during oxidation in CO_2 or H_2O, leading to formation of a few large pits, whereas oxidation in O_2 may lead to the more detrimental condition of a high density of small pits. No effect of reaction temperature on the strengths of the graphics was observed. Attempts to fit strength-burnoff data to a standard expression were only partially successful. Much improved fits were obtained when this expression was modified to account for the development of the micro/mesopore network during oxidation. (30 refs.)

73168 The use of acoustic emission techniques to monitor fracture processes in high strength precipitation hardened aluminum alloys. A.Arieli, R.P.Wells, M.A.Hamstad, A.K.Mukherjee (Dept. of Mech. Engng., Univ. of California, Davis, CA, USA).
Mech. Mater. (Netherlands), vol.2, no.1, p.1-7 (April 1983).
The ductile fracture of dispersion hardened aluminum alloy containing brittle intermetallic inclusions is briefly reviewed. The effect of the size, distribution and chemical composition of the inclusions in affecting the matrix fracture behavior is discussed. The potential of acoustic emission techniques in being able to discriminate between different microstructures produced by various thermomechanical treatment is emphasized. It is shown that processes that affect dislocation motion, i.e. cold work, precipitation, solute atom diffusion, etc., also affect the acoustic response, thus making the AE technique extremely useful for the study of flow and fracture behavior of aluminum alloys. (11 refs.)

73169 Fracture strains in biaxially loaded 2024 aluminum tubes. M.G.Stout, S.S.Hecker (Los Alamos Nat. Lab., Los Alamos, NM, USA).
Mech. Mater. (Netherlands), vol.2, no.1, p.19-22 (April 1983).
2024 aluminum tubes, heat treated to a T6 and T8 temper, were proportionally loaded to failure with combinations of tension and internal pressure. The authors measured diffuse instability and fracture strains and compared these to the ductile fracture model of Ghosh (1976). Agreement was quite good. Fracture strains measured in axial tension and pure hoop tension were equivalent even though anisotropies were observed in the plastic deformation of the tubes. (7 refs.)

73170 Statistical modeling of fatigue-crack growth in a nickel-base superalloy. J.N.Yang (School of Engng. & Appl. Sci., George Washington Univ., Washington, DC, USA), G.C.Salivar, C.G.Annis,Jr..
Eng. Fract. Mech. (GB), vol.18, no.2, p.257-70 (1983).
Two fracture mechanics-based statistical models for the fatigue crack propagation of engine materials are developed. The models are applied to fatigue crack growth rate data for IN100, a nickel-based superalloy used in F100 engine disks, at various elevated temperatures, loading frequencies and stress ratios. The lognormal and the randomized parameter models allows the incorporation of the statistical variability associated with crack growth data into the life prediction process. The statistical distributions of (i) the crack growth rate, (ii) the propagation life to reach a given crack size, and (iii) the crack size at any given service life have been derived. A correlation analysis is performed to compare the results of the statistical models with test data. The correlation is demonstrated to be very good. (4 refs.)

73171 Estimating the statistical properties of crack growth for small cracks. P.W.Hovey, J.P.Gallagher, A.P.Berens (Univ. of Dayton Res. Inst., Dayton, OH, USA).
Eng. Fract. Mech. (GB), vol.18, no.2, p.285-94 (1983).
A series of statistical studies were conducted on two sets of fatigue crack growth data which were generated under variable amplitude loading from cracks that initiated in 7475-T7351 aluminum down in the bore of typical aircraft quality prepared holes. The study considered fatigue crack growth (life) behavior and fatigue crack rate behavior. Generally, the study showed that small crack growth behavior was similar to that observed for larger cracks and that a stress intensity factor parameter could be used to describe the mean trend of the fatigue crack growth rate behavior via a power law relationship. (10 refs.)

73172 Crack closure studies under constant amplitude loading. S.Chand, S.B.L.Garg (Mech. Engng. Dept., Motilal Nehru Regional Engng. Coll., Allahabad, India).
Eng. Fract. Mech. (GB), vol.18, no.2, p.333-47 (1983).
Crack closure experiments were performed on 6063-T6 Al-alloy using a COD-gauge for various load ranges and stress ratios. Experimental results show that for a given stress ratio, R, the crack closure load goes on decreasing as crack length increases (or K_{max} increases) and reaches even below minimum load level at higher values of stress ratios. On the basis of these experimental results, a model for effective stress intensity range ratio U, which is found to be a function of stress ratio R and K_{max}, is developed. (21 refs.)

73173 The effect of stress relaxation on the tearing of vulcanized rubber. R.S.Rivlin (Lehigh Univ., Bethlehem, PA, USA), A.G.Thomas.
Eng. Fract. Mech. (GB), vol.18, no.2, p.389-401 (1983).
A two-network model for an elastomer in which stress relaxation has taken place, similar to that proposed by Green and Tobolsky (1946) is used to calculate the incipient characteristic energy for tearing and to study its dependence on the number of chain segments in each of the two networks, the number of links in these chain segments, the extension at which the stress relaxation took place and the orientation of the tear. (13 refs.)

73174 Near-threshold fatigue crack propagation of several high strength steels. T.L.Mackay, B.J.Alperin, D.D.Bhatt (Douglas Aircraft Co., McDonnell Douglas Corp., Long Beach, CA, USA).
Eng. Fract. Mech. (GB), vol.18, no.2, p.403-16 (1983).
In support of Douglas Aircraft Co. structural damage tolerance analysis, crack propagation rates were measured in humid air from 10^{-8} to 10^{-3} mm/cycle of several high strength martensitic steels at stress ratios of $R=0.1$ and $R=0.5$. Increasing the stress ratio was found to decrease the threshold stress intensity. Increasing the tensile yield material strength in these quench and tempered steels resulted in a nearly linear inverse relationship with the threshold stress intensity. The threshold stress intensity appeared to be independent of the fracture toughness of the alloy steel. (6 refs.)

73175 Plastic deformation in the course of fracture of ferrite-pearlitic steels. M.N.Georgiev, V.Yu.Dogadushkin, N.Ya.Mezhova, V.K.Minaev, L.P.Strok (All-Union Sci.-Res. Inst. of Railway Engrs., USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.571-5 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
X-ray and electron fractography methods were used to study some characteristics of plastic deformation of fractured surfaces of steels with the ferrite-pearlite structure as a function of the nature of loading and test temperature. The results indicated that fatigue fracture was a very brittle fracture from the energy point of view. Cooling indicated the occurrence of mechanisms typical of single loading and stopping of the processes of ordering of the dislocation structure. (6 refs.) *A.T.*

73176 Hydrides and delayed hydrogen cracking in zirconium and its alloys. D.O.Northwood, U.Kosasih (Dept. of Engng. Materials, Univ. of Windsor, Windsor, Ontario, Canada).
Int. Met. Rev. (GB), vol.28, no.2, p.92-121 (1983).
A critical review is presented of published data on hydrogen, hydrides, and delayed hydrogen cracking (or hydrogen-induced delayed cracking, HIDC) in zirconium and its alloys. It is shown that factors such as solution temperature, cooling rate, and applied or residual stresses greatly affect the hydride morphology and orientation. The most detrimental hydride morphology is shown to be that when the hydride is oriented normal to the applied stress and has the morphology of a continuous sheet. Although knowledge of the mechanism(s) of delayed hydrogen cracking has improved greatly in the past five years, further research is needed to provide a better understanding of the process. The review concludes with a discussion of delayed hydrogen cracking in the practical case of nuclear-reactor pressure tubes, and presents possible remedies to ensure no further reoccurrence of the phenomenon in commercial reactors. (143 refs.)

73177 Fragmentation behavior of Armco iron and HF-1 steel explosive-filled cylinders. W.Mock,Jr., W.H.Holt (Naval Surface Weapons Center, Dahlgren, VA, USA).
J. Appl. Phys. (USA), vol.54, no.5, p.2344-51 (May 1983).
The fragmentation response of explosive-filled cylinders of Armco iron and HF-1 steel with two heat treatments has been determined. The cylinders were filled with cast-in-plane composition B explosive and detonated. At least 99% of the metal mass was recovered in all the experiments. The recovered fragments had both brittle and shear fracture surfaces. The average fragment mass for the Armco iron and HF-1 steel experiemnts was 6.3 and 0.9 g, respectively. Average engineering radial strain values for the fragments were 0.35 and 0.12 for Armco iron and HF-1 steel, respectively. A scheme was devised for characterizing the recovered fragments according to their cylindrical and fracture surfaces. Fragment mass distributions are presented for the characterized fragments. (11 refs.)

73178 The effect of non-uniform bending deformation on the stability of circumferential growth of through-wall cracks in brass tubes. E.Smith, M.J.Wilding (Manchester Univ., Manchester, England).
J. Mech. & Phys. Solids (GB), vol.31, no.3, p.223-9 (1983).
Experimental results on the stability of circumferential growth of through-wall cracks in brass tubes, show that non-uniform bending can adversely affect the crack stability criterion. The results are relevant to the important technological problem of crack stability in 304 stainless steel pipes used in Boiling Water Reactors. (3 refs.)

73179 Response of cracks in structural materials to short pulse loads. H.Homma, D.A.Shockey (Dept. of Metall. & Fracture Mech., SRI Internat., Menlo Park, CA, USA), Y.Murayama.
J. Mech. & Phys. Solids (GB), vol.31, no.3, p.261-79 (1983).
Cracks in single-edge-notched strip specimens of 4340 steel, 1018 steel, and 6061-T651 aluminum were loaded by tensile pulses of various amplitudes and durations to determine critical stresses for crack instability. The results were not well described by static fracture mechanics, but were in accord with behavior inferred from considerations of crack-tip stress intensity histories. (21 refs.)

73180 Dynamic fatigue of brittle materials containing indentation line flaws. B.L.Symonds, R.F.Cook (Dept. of Appl. Phys., School of Phys., Univ. of New South Wales, Kensington, Australia), B.R.Lawn.
J. Mater. Sci. (GB), vol.18, no.5, p.1306-14 (May 1983).
A study is made of the dynamic fatigue response of brittle materials containing indentation-induced line flaws. The theoretical fracture mechanics of 'median' crack evolution to failure under applied tension are first developed, with special emphasis on the role of residual contact stresses. In particular, it is shown that use of fatigue curves to evaluate the exponent in an assumed power-law crack velocity function may result in systematic error, by as much as a factor of two, if proper account is not taken of this residual contact contribution. Data from strength tests on soda-lime glass bars in water, using a tungsten carbide cutting wheel to introduce the median pre-cracks, confirm the basic predictions. The results suggest that extreme care needs to be exercised when using surfaces with a contact history, e.g. as with machining damage, in fatigue test programmes for materials analysis. (25 refs.)

73181 The influence of morphology and molecular weight on ductile-brittle transitions in linear polyethylene. N.Brown (Dept. of Materials Sci. & Engng., Univ. of Pennsylvania, Philadelphia, PA, USA), I.M.Ward.
J. Mater. Sci. (GB), vol.18, no.5, p.1405-20 (May 1983).
The tensile behaviour of linear polyethylene was examined over a wide range of temperatures. Samples were prepared from low and medium molecular weight polymer with different morphologies, by varying the initial crystallization conditions. It was found that the temperature of the ductile-brittle transition was markedly different for different samples. In particular, low molecular weight polymer crystallized at a low degree of supercooling, showed brittle behaviour over most of the temperature range, with a ductile-brittle transition near to room temperature. Rapidly quenched material, where the degree of supercooling is high, showed a very low ductile-brittle transition temperature, especially in high molecular weight polymer. The reasons for these differences in behaviour are discussed both at a phenomenological level and in terms of known structural differences between the different materials examined. (20 refs.)

73182 Impact strength of En8 steel diffusion bonds. C.E.Thornton, E.R.Wallach (Dept. of Metall. & Materials Sci., Univ. of Cambridge, Cambridge, England).
J. Mater. Sci. (GB), vol.18, no.5, p.1433-42 (May 1983).
The use of diffusion bonding for the joining of steel is not widespread due partly to the large number of alternative welding processes and partly to a lack of information on mechanical properties of the resultant bonds. Data are provided on both tensile and impact properties of diffusion bonds in a plain carbon steel containing 0.4% C. Several hypotheses are proposed for the observed low impact properties and one of these, the presence of a planar layer of ferrite at the bond line, is discounted. (9 refs.)

73183 On the correlation between solid-particle erosion and fracture parameters in SiC. J.L.Routbort, Hj.Matzke (European Inst. for Transuranium Elements, Karlsruhe, Germany).
J. Mater. Sci. (GB), vol.18, no.5, p.1491-6 (May 1983).
The fracture toughness, K_{Ic}, for a hot-pressed SiC and three types of reaction-bonded SiC has been measured using the Hertzian indentation technique with spherical indentors whose radii varied from 2.5 to 10 mm. Excellent agreement between the toughness measured by this technique and the published K_{Ic} value measured using double torsion is obtained for the hot-pressed SiC. The Vickers hardness, H, which was also measured and K_{Ic} have been used to predict the solid-particle erosion rate, ΔW, given by $\Delta W \propto H^a K_c{}^b$ where the values of the exponents a and b depend on the details of the erosion model. The predicted rates are not in agreement with the measured rates. This discrepancy is probably due to the fact that the models are insensitive to microstructure. (16 refs.)

73184 Some aspects of crack growth and failure in fibre reinforced composites. J.G.Morley (Wolfson Inst. of Interfacial Technol., Univ. of Nottingham, Nottingham, England).
J. Mater. Sci. (GB), vol.18, no.5, p.1564-76 (May 1983).
A theoretical analysis, previously developed to deal with the mechanics of matrix cracking in unidirectional composites and with transverse ply cracking in cross ply laminates, has been developed further to deal with the tensile failure of unidirectional fibrous composites in which the fibres have a known distribution of strengths. It is proposed that, under the application of a tensile load, stable transverse cracks are formed which originate from regions of initial damage and which become unstable at some critical strain value. The model takes account of various parameters including the interfacial fibre/matrix debonding energy, the residual frictional shear strength of the debonded interface and the elastic properties of fibres and matrix. The relevance of the model to the study of delayed fracture in fibrous composites is discussed. The modification of this model is used to predict the initial cracking strains for a wide range of CFRP laminate geometries and initial crack size. Some aspects of the mechanics of crack extension across interply interfaces are discussed. (10 refs.)

73185 Fracture toughness/Young's modulus correlation for low-density fibrous silica bodies. D.J.Green (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.288-92 (April 1983).
Fracture toughness and static Young's modulus were measured for the low-density silica fiber materials used as tiles in the thermal protection system of the Space Shuttle. The fracture behavior was found to be in excellent agreement with a previously formulated micromechanical model (D.J. Green et al. see ibid., vol.65, no.3, p.138-41, 1982) and allowed both (density) classes of tile material to be correlated to a single function. A similar correlation was also found between strength and Young's modulus, which is the basis of a nondestructive evaluation test for these materials. It was shown that the value of Young's modulus determined from a dynamic test can be substantially greater than that determined in a static mechanical test. This effect must be taken into account in the correlation. Finally, it was also determined that these materials have significant variations in K_c, both within and between production units, so that the strength variability in these materials is dependent on both fracture toughness and flaw-size variations. (18 refs.)

73186 Relation of load to radial crack length for spherical indentations in hot-pressed ZnS. H.P.Kirchner, J.A.Ragosta (Ceramic Finishing Co., State College, PA, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.293-6 (April 1983).
Hot-pressed ZnS was indented by spherical indenters of various radii. The relation of the load (P) and radial crack length (c_r) was better modeled by $P \propto d_i c_r{}^{1/2}$, where d_i is the indentation diameter, than by $P \propto c_r{}^{3/2}$. (17 refs.)

73187 Mechanical properties of sintered and nitrided laser-synthesized silicon powder. S.C.Danforth, J.S.Haggerty (Dept. of Materials Sci. & Engng., MIT, Cambridge, MA, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.C58-9 (April 1983).
Pure and boron-doped silicon powders made by laser-heated gas-phase synthesis were densified by pressureless sintering and then nitrided. Modulus of rupture, hardness, and fracture toughness were measured for reaction-bonded Si_3N_4 samples made from these powders and for other standard materials for comparison. (12 refs.)

73188 X-ray diffraction studies of thermally shocked periclase. R.Vasudevan, H.Schneider, A.Majdic (Forschungsinst. der Feuerfest-Industrie, Bonn, Germany).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.C68-9 (April 1983).
X-ray line profile analyses were used to study the effect of thermal shock on periclase (MgO) powders of varied sieve size. Thermal shock does not produce significant microfragmentation; the crystallite size appeared to be ≥ 150 nm. Microstrain is very low at grain sizes <0.10 mm, rises sharply up to ≈ 0.8 mm, and tends to saturate at $\approx 1 \times 10^{-3}$ at sieve sizes above 3 mm. (10 refs.)

73189 Comment on 'Toughening of glasses by metallic particles' [and reply]. S.C.Kunz (Composites & Polymer Mech. Div., Sandia Nat. Labs., Albuquerque, NM, USA), V.Kostic, P.S.Nicholson.
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.C73-4 (April 1983).
Comments on the work of V.V. Krstic et al. (see ibid., vol.64, no.9, p.499-504, 1981) concerning the toughening of glass by metallic particles. The value used for the thermal expansion coefficient of aluminium and the calculations of theoretical toughness values are criticized. V.V. Krstic and P.S. Nicholson give their reply. (3 refs.)

73190 Scanning electron microscope and ferromagnetic resonance investigations of fractured metglas 2826 alloy. R.S.Parashar, C.S.Sunandana, A.K.Bhatnagar (School of Phys., Univ. of Hyderabad, Hyderabad, India).
J. Non-Cryst. Solids (Netherlands), vol.55, no.2, p.301-5 (May 1983).
The authors have investigated the effect of various fracture treatments of metallic glass ribbons on the FMR spectra and have tried to evolve a method which results in minimum damage. Surface damage near the fractured specimens was examined through a scanning electron microscope. (6 refs.)

73191 Strength and toughness of various types of concrete. W.Koyanagi, K.Rokugo, Y.Uchida, H.Iwase (Faculty of Engng., Gifu Univ., Gifu, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.353, p.188-94 (Feb. 1983). In Japanese.
The failure characteristics such as strength and toughness of various types of concretes including steel fiber reinforced concrete and light weight concrete, were investigated in order to contribute to the establishment of evaluating methods of the characteristics. The following results were obtained. The shear strength measured from the direct double shear tests was proportional to the tensile strength. The absorbed energy ratio W_{cq}/W_{cp} in compression was found to be a useful parameter to indicate the failure behaviour of concrete, that is, how suddenly concrete loses its load carrying capacity after the maximum loads are reached. W_{cp} indicates the absorbed energy of a specimen up to the point of maximum load P_{max}, and W_{cq} the one up to the failure point, where the load descends to 1/3 of P_{max}. The ratio W_{cq}/W_{cp} was well related to the brittleness index, which is the ratio of compressive strength σ_c to tensile strength σ_t. The effect of steel fiber reinforcement on the improvement of concrete toughness was greater in flexure than in compression. (7 refs.)

73192 Fatigue life of concrete under varying repeated compressive load. S.Nishibayashi, K.Yamura, S.Inoue (Faculty of Engng., Tottori Univ., Tottori, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.353, p.202-7 (Feb. 1983). In Japanese.
In order to investigate the fatigue life of concrete under varying repeated load, several stress fatigue tests were performed. In these tests, concrete cylinder specimens were subjected to the repeated load in which load levels were selected as to be between a constant minimum stress level and five different maximum stress level S_j (72~82 percent of the ultimate static strength at each interval of 2.5%). The triangular-, normal-, uniform-, and exponential-distributions were used as the shape of the stress block for the varying repeated load. The order of the applied maximum stress level was selected at random. At each test condition, the sum of cycles ratio follows a logarithmic normal distribution. Miner's rule may possibly be applied to predict the fatigue life under varying repeated load in which the magnitude of stress is changed quite frequently. (7 refs.)

73193 Thermal shock resistances and fracture toughnesses of SiC and B_4C disks at elevated temperature. S.Sato, K.Tobita, M.Kurata.
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.19-26 (1982).
Fracture mechanics properties for thermal shock are determined of five varieties of silicon carbides and a boron carbide at elevated temperature. The measurements are carried out using the disk testing method including the fracture toughness, thermal shock resistance and thermal shock fracture toughness. The obtained results are discussed with respect to the manufacturing conditions of the specimens. (10 refs.)

73194 Fracture mechanics properties for thermal shock of the mesophase pitch carbons during the graphitizing heat treatment process. S.Sato, M.Ishihara, O.Watanabe, N.Ogata.
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.27-33 (1982).
The authors describe experimental results concerning the temperature dependencies of heat treatment on the strength and fracture toughness for thermal shock during the graphitizing heat treatment process of two types of high density and high strength graphite, called metaphite. The metaphites were recently produced from mesophase pitch with fine mosaic structures which were obtained by appropriate heat treatments for residual pitch in the oil cracking process. The examined specimens are the baked carbons and the graphitized ones of the hard carbon origin-MF301 and the soft carbon origin-MF306. The measured fracture mechanics properties include diametral compressive strength, mode I and II fracture toughness, thermal shock resistance and thermal shock fracture toughness by means of the disk testing method in addition to usual mechanical properties. (8 refs.)

73195 Thermal shock resistance and fracture toughness of graphite with different arrangements of coke grain size and porosity. S.Sato, M.Ishihara, Y.Inoue, S.Kiyono.
J. Fac. Eng. Ibaraki Univ. (Japan), no.30, p.35-42 (1982).
The authors discuss the fracture mechanics properties as two functions of the mean grain size G and the mean porosity P in three grades of electrode graphite, which were made from well defined grain arrangements. The fracture properties are measured primarily by means of a series of disk tests which include diametral compressive strength σ_{HC}, mode I fracture toughness K_{IC}, thermal shock resistance $\Delta(=\sigma_t k/E\alpha$, σ_t:tensile strength, k:thermal conductivity, E:Young's modulus, and α:coefficient of thermal expansion) and thermal shock fracture toughness $\nabla(=K_{Ic}k/E\alpha)$. Knudsen type expressions on G and P for Δ and ∇ are formulated and the optimum arrangement of coke grain size are discussed. (22 refs.)

73196 Compression testing and cracking of plain concrete. N.G.Shrive (King's Coll., Univ. of London, London, England).
Mag. Concr. Res. (GB), vol.35, no.122, p.27-39 (March 1983).
Flaws such as pores and voids are present in cement paste, and therefore in concrete. These flaws act as stress-raisers and cause the initiation of cracks in compressive stress fields. By analysing the stress state in compressive test specimens—recognizing that testing machines apply displacement conditions—and examining the stresses which may then exist around a spherical void, it is possible to explain the typical cracking patterns observed in such specimens. It is also possible to explain the cracking patterns and apparent changes in strength observed under externally applied biaxial stress conditions. This analytical work is restricted to elastic isotropic media and spherical voids, so the potential effect of aggregate particles is examined. Aggregate is shown to cause stress variation on a local basis, which may aid crack formation close to aggregate particles, and the extension of cracks around aggregate/cement paste interfaces. (15 refs.)

73197 Grain boundary sliding and stress concentration during creep. T.Watanabe (Dept. of Materials Sci., Tohoku Univ., Sendai, Japan).
Metall. Trans. A (USA), vol.14A, no.4, p.531-45 (April 1983). (Symposium on 'The Role of Trace Elements and Interfaces in Creep Failure', Dallas, TX, USA, 14-18 Feb. 1982).
Importance of grain boundary sliding to creep intergranular fracture is focused. Previous metallographic and fractographic studies of creep intergranular fracture on metal bicrystals and polycrystals are briefly reviewed in order to show the close relationship between grain boundary sliding and fracture. Deformation ledge and migration irregularity are shown to be potential sites of stress concentration and crack nucleation on sliding grain boundaries without particles. The effect of grain boundary structure on creep intergranular fracture is discussed on the basis of the effect of grain boundary structure on sliding, the contribution of sliding to the overall creep deformation, and a sliding-fracture diagram. Recent observations of the effect of grain boundary structure on creep intergranular fracture on alpha Fe-Sn alloy polycrystals are shown. (55 refs.)

73198 High temperature embrittlement of Ni and Ni-Cr alloys by trace elements. C.L.White, J.H.Schneibel, R.A.Padgett (Metals & Ceramics Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.595-610 (April 1983). (Symposium on 'The Role of Trace Elements and Interfaces in Creep Failure', Dallas, TX, USA, 14-18 Feb. 1982).
The effects of Sb, S, and Zr additions on the creep properties of Ni and Ni+20 pct Cr are reported. Antimony and tin additions (~1 wt. pct) induce extensive grain boundary cavitation in nickel, while smaller antimony additions had little effect on Ni+20 pct Cr. Addition of 0.11 pct Zr to Ni+20 pct Cr greatly inhibited grain boundary cavitation and reduced its Coble creep rate. Auger electron spectroscopy of cavitated specimens provided direct evidence of impurity segregation to cavity surfaces. Residual sulfur segregated most strongly, and was observed on cavity surfaces in all cavitated specimens. Tin segregated somewhat less intensely than sulfur, and antimony segregated only slightly. Segregation of antimony and sulfur to uncavitated portions of Ni+1 pct Sb grain boundaries was also observed. These results are discussed in terms of segregation effects on energetic and transport properties of the grain boundaries and cavity surfaces. (64 refs.)

73199 Analyzing statistical variability of fracture properties. T.A.Bishop, A.J.Markworth, A.R.Rosenfield (Battelle-Columbus, Columbus, OH, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.687-93 (April 1983).
A recently developed statistical analysis is applied to the estimation of lower-bound Charpy V-notch impact energies. Scatter of the impact-energy-absorption data, at any given temperature, is described using a two-parameter Weibull distribution, with the parameters allowed to vary with temperature. Values for the parameters are obtained using standard linear-regression techniques. As a result, the analysis naturally yields the temperature dependence of the *p*th percentile of the impact-energy distribution. Data with both large and small scatter are analyzed using this procedure. (13 refs.)

73200 The enhancement of hydrogen attack in steel by prior deformation. S.F.Clugston, J.R.Weertman (Dept. of Materials Sci. & Engng., Northwestern Univ., Evanston, IL, USA), P.G.Shewmon.
Metall. Trans. A (USA), vol.14A, no.4, p.695-9 (April 1983).
An investigation has been made of the cause of enhancement of hydrogen attack (HA) by prior cold working. Bars of 1020 Si-killed steel deformed in three point bending were found to contain microcracks at ferrite/ferrite grain boundaries containing cementite inclusions and at ferrite/pearlite boundaries. Very long cementite plates crack, but shorter cementite inclusions ($\leq\simeq 2\ \mu m$) suffer decohesion from the matrix at or near the inclusion ends. The observed anisotropy of microcracking with respect to grain boundary orientation and sign of the deformation stress can be understood in terms of the stress state at the inclusion/matrix interface during deformation. The microcracks are not eliminated by an annealing treatment which is known to cancel the effect of deformation on HA. It is concluded that residual stresses arising from the difference in deformability between cementite particles and matrix are responsible for the influence of deformation on HA. (12 refs.)

73201 Effects of hydrogen on near-threshold crack propagation in niobium. S.Fariabi, A.L.W.Collins, K.Salama (Univ. of Houston, Houston, TX, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.701-7 (April 1983).
The effects of hydrogen on near-threshold fatigue crack growth rate have been investigated in niobium at room temperature. Fatigue tests were performed on a hydrogen-free specimen as well as specimens containing hydrogen in solid solution and in the form of hydride. Specimens were tested using a tension-tension loading cycle at a frequency of 4 Hz and two load ratios of 0.05 and 0.4. The results show that the threshold stress-intensity factor ΔK_{th} decreases with the addition of hydrogen and reaches a minimum at a hydrogen concentration approximately equal to the solubility limit of hydrogen in niobium. As the hydrogen concentration exceeds the solubility limit, ΔK_{th} increases with the increase of the amount of hydrogen dissolved in the specimen. Analysis of this behavior suggests that stress-induced hydride cannot be responsible for the embrittlement of niobium with hydrogen, and dislocation-hydrogen interaction plays an important role in the embrittlement process. SEM metallography studies also confirm the importance of dislocation in the embrittlement of niobium by hydrogen. (37 refs.)

73202 Crack propagation of high strength steels in a gaseous hydrogen atmosphere. M.Nakamura, E.-I.Furubayashi (Tsukuba Labs., Nat. Res. Inst. for Metals, Ibaraki, Japan).
Metall. Trans. A (USA), vol.14A, no.4, p.717-26 (April 1983).
The crack propagation behavior in delayed fracture was investigated at room temperature under pressure up to 784 kPa of hydrogen gas for high strength steels with the tensile strength of 1500 or 2000 MPa. For specimens with the tensile strength of 1500 MPa, the crack propagation rate *da/dt* increased with C content from 0.21 to 0.42 wt. pct, and then it decreased with increasing C content up to 0.53 wt. pct. *da/dt* increased rapidly with Mn content from 0.009 to 0.84 wt. pct, and it increased gradually with Mn content from 0.84 to 2.13 wt. pct. The permeation flow of hydrogen from the crack tip surface could be quantitatively estimated from the dependence of *da/dt* upon the hydrogen pressure based on the simple assumption. In addition to the ground boundary embrittlement caused by tempering and/or hydrogen, the permeation flow of hydrogen was used to explain qualitatively the dependence of *da/dt* upon C or Mn content. (28 refs.)

73203 S-N curve inversion of nickel-base superalloy at elevated temperature. R.R.Paulson, L.G.Fritzemeier, J.K.Tien (Henry Krumb School of Mines, Columbia Univ., New York, NY, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.727-31 (April 1983).
Stress controlled tensile fatigue behavior of a representative nickel-base superalloy, Udimet 115, was studied at 760°C and 1 Hz while holding the maximum stress constant. An inversion in the S-N curve was observed within 10^4 cycles, in contrast to normal S-N behavior at ambient temperatures. A detailed analysis of the strain response to a trapezoidal applied stress waveform indicated that the inversion is consistent with increasing creep strains due to increasing mean stresses. Fractographic observations were also found to be consistent with the inversion in that, at higher mean stresses, intergranular fracture replaced the usual stage II-type intragranular fracture associated with fatigue failure in these planar-slip alloys. The results are also discussed with respect to the three regimes of dynamic creep and the observed plastic increments and anelastic strains. (12 refs.)

73204 Microstructures and mechanical properties of hot isostatically pressed powder metallurgy alloy APK-1. T.L.Prakash, Y.N.Chari, E.S.Bhagiradha Rao, R.Thamburaj (Defence Metall. Res. Labs., Hyderabad, India).
Metall. Trans. A (USA), vol.14A, no.4, p.733-42 (April 1983).
The influence of hot isostatic pressing (HIP) and heat treatment parameters on the microstructure and mechanical properties of powder metallurgy alloy APK-1 (a low carbon modification of Astroloy) has been investigated. Poor mechanical properties result if carbide networks are present along the prior particle boundaries (PPBs). These networks which form during powder consolidation can be avoided by manipulating HIP parameters. Heat treatments which produce a large volume fraction of fine γ' make this alloy susceptible to environment-assisted tensile embrittlement around 760°C. (10 refs.)

73205 The effect of temperature, specimen size, and geometry on the fracture toughness of a 3 pct NiCrMoV low pressure turbine disc steel. N.B.Shaw, G.M.Spink (Sci. Services Dept., CEGB, Harrogate, England).
Metall. Trans. A (USA), vol.14A, no.4, p.751-9 (April 1983).
The variation of fracture toughness with temperature and specimen size of a 3 pct NiCrMoV LP disc steel has been investigated over the temperature range −100 to +100°C using compact tension and single-edge-notched bend geometries. A number of large 'half-disc' three point bend specimens were also tested. Toughness increased up to a transition temperature coinciding with the onset of stable ductile tearing prior to instability. Below this temperature fracture could be described by established linear elastic or post yield fracture analyses. Above this temperature failure was by plastic collapse. The transition temperature decreased with decreasing specimen size, and at similar thicknesses was lower for the bend geometry than for the compact tension so that it was not possible to predict the fracture behavior of the full size service component from small scale tests in the transition region. A further complicating feature was the extreme scatter of some duplicate test results below the transition temperature. The implications for toughness testing in the transition region are discussed. The data obtained have been combined with published data for similar steels to derive an equation which describes the variation of fracture toughness with temperature for steels of this type. (18 refs.)

73206 Some solid-state properties of blends of polyethylene terephthalate and polyamide-6,6. M.R.Kamal, M.A.Sahto (Dept. of Chem. Engng., McGill Univ., Montreal, Quebec, Canada), L.A.Utracki.
Polym. Eng. & Sci. (USA), vol.22, no.17, p.1127-37 (mid-Dec. 1982). (Second Mini-Symposium on Polymer Blends, 'Polyblends '82', Montreal, Canada, 20 April 1982).
Polymer blends incorporating polyamide-6,6(PA) and polyethylene terephthalate (PET) and having the following PA wt.% concentrations were prepared: 0, 5, 10, 25, 30, 35, and 100. Samples were obtained by molding in a reciprocating-screw injection-molding machine. The samples were annealed to minimize frozen-in stresses without increasing the crystallinity level in the material. Melting and heat-of-fusion data, obtained with the differential scanning calorimeter, suggest an overall increased crystallinity in the blends, as indicated by a significant excess heat of fusion. Whereas the neat polymers exhibited ductile failure under both tensile and impact testing conditions, the blends showed brittle behavior. The abrasion resistance of the blends was inferior to that observed for PET but higher than the resistance of PA. (51 refs.)

73207 High temperature mechanical behaviour of silicon nitrides (Si_3N_4, Sialon). G.Orange, G.Fantozzi (Groupe d'Etude de Metall. Phys. et de Phys. des Materiaux, Villeurbanne, France).
Rev. Chim. Miner. (France), vol.20, no.1, p.20-36 (1983). In French.
Nitrogen ceramics, and especially silicon nitride ceramics, have a unique combination of properties which has encouraged their potential application as structural components in high temperature engineering applications. The high temperature mechanical behaviour of different varieties of silicon nitride: a reaction-bonded silicon nitride has been determined. (RBSN), a hot-pressed silicon nitride (HPSN), and a pressureless sintered Sialon. The elastic modulus, the flexural strength and the fracture toughness have been measured up to 1500°C, in inert and in air atmosphere. The mechanical behaviour of these different varieties is discussed with regard to the microstructure. (28 refs.)

73208 Sintered boron—production and properties. II. Mechanical and thermophysical properties. R.A.Andrievskii, I.A.Bairamashvili, L.N.Dement'ev, P.V.Zubarev, A.G.Lanin, Yu.I.Soloev, M.L.Taubin, M.A.Fedotov (Moscow Inst. of Fine Chem. Technol., Moscow, USSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.702-5 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.24-7 (Sept. 1982). [received: March 1983]
For pt.I see ibid., vol.27, no.8, p.27 (1982). Specimens of 15-35% porosity were produced by sintering in argon. Hardness in the temperature range 20-1000°C was determined using a modified IMASh-300 machine. Compressive strength σ_c measurements were made on 3-mm-square, 6-mm-high specimens. Transverse rupture strength σ_{tr} in the temperature range 20-1900°C was measured in a vacuum corresponding to $1.3.10^{-4}$ Pa. Diametral compression ('indirect extension') was studied on 12-mm-diameter, 3- to 6-mm-high specimens at room temperature. Young's modulus was measured by an ultrasonic method at room temperature. Measurements of the coefficient of linear expansion (CLE) α_t of 3-mm-square, 12-mm-long specimens were made. The thermal properties (thermal conductivity λ, heat capacity C_p, and thermal diffusivity *a*) of 12-mm-diameter, 15-mm-high cylindrical specimens were determined in a dynamic calorimeter. (17 refs.)

73209 Laws of plastic strain and fatigue fracture of metals in torsion. V.T.Troshchenko, V.I.Dragan (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.569-76 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.3-10 (May 1982). [received: May 1983]
Three periods are distinguished in fatigue crack propagation of steels. The first period is connected with crack propagation along or across the specimen axis, with shear stresses being determining in this case. The crack propagates in the second period at a 45° angle to the specimen axis and its growth is governed by normal stresses. In the final period the crack again begins to grow in the plane of the maximum shear stresses. This is followed by final fracture. The amount of plastic strain per cycle during the plastic-strain stabilization stage at stresses exceeding the endurance limit is determined by the dimensions and number of microcracks. Plastic strain, leading to the appearance of a closed hysteresis loop in the coordinates stress-strain during cyclic loading, can be used as a measure of fatigue damage at the stage of fatigue crack nucleation. (5 refs.)

73210 Allowing for strength anisotropy in estimating the rupture strength of actual tubes in a plane stress state. E.A.Myakotin (Inst. of Mech., Moscow State Univ., Moscow, USSR).
Strength Mater. (USA), vol.14, no.5, p.589-93 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.20-3 (May 1982). [received: May 1983]
Previous results of creep rupture tests of high-strength steel tubes, subjected to low-temperature thermomechanical treatment (LTMT), in axial and peripheral tension showed that not only was strength as a whole increased, but strength anisotropy also appeared—the ratio of axial to peripheral strength ranged from 1.25 to 2.5, depending on the conditions of the LTMT. In the present work the feasibility is examined of improving the accuracy of predictions of the high-temperature rupture strength of thin-walled tubes in complex stress states by allowing for strength anisotropy. (7 refs.)

73211 Influence of the type of solidification of a cast nickel alloy of the ZhS6 family on its high temperature strength. E.R.Golubovskii, I.P.Bulygin, L.N.Timofeeva, E.Yu.Shershenkova.
Strength Mater. (USA), vol.14, no.5, p.635-41 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.59-64 (May 1982). [received: May 1983]
The authors present the results of an investigation of the stress-rupture strength and ductility of cast ZhS6U alloy with equiaxial and directed structures. Directed solidification of ZhS6U alloy not only increased the average values of the characteristics of high temperature strength but also reduced their dispersion in comparison with the similar characteristics in the equiaxial structure. In addition, with an increase in the test base and temperature, the advantage in high temperature strength of the directed structure increased. (6 refs.)

73212 Discreteness and self-similarity of failure in stable fatigue crack growth. V.S.Ivanova (A.A. Baikov Inst. of Metall., Moscow, USSR).
Strength Mater. (USA), vol.14, no.5, p.675-84 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.91-9 (May 1982). [received: May 1983]
On the basis of approaches of linear fracture mechanics and the theory of self-similarity it has been shown that the effect of the external factors on the cracking resistance criteria can be reduced to a single factor, i.e. the degree of constraint of plastic deformation characterized by parameter $Q=(\sigma_{11})_{max}/\sigma_T$. As the criterion controlling the transition from quasielastic self-similar to elasto-plastic self-similar crack propagation, it is proposed to use the Huber-Mises criterion. The K_{I*}-m diagram linking the threshold values of K_{I*} with coefficient m which characterizes the crack growth retardation capability has been proposed. The regions of the K_{I*} values and of the corresponding values of m which correspond to self+similar elastoplastic crack growth have been defined. (25 refs.)

73213 Application of the kinetic strength concept to determination of the longevity of specimens with a stress raiser under static load. A.I.Ravikovich.
Strength Mater. (USA), vol.14, no.5, p.690-4 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.103-7 (May 1982). [received: May 1983]
The author examined one of the possible approaches to the determination of the longevity of specimens with a stress raiser by computational means on the basis of the kinetic strength concept. It is known that the kinetic characteristics obtained in processing experimental data on the longevity of smooth specimens can be used to calculate the longevity of specimens with a stress raiser. A method of computing the longevity of these specimens under cyclic loading is proposed. The results of experimental investigation of the longevity of smooth specimens and specimens with a stress raiser under cyclic tension at a frequency of 7.45 cycles/min and test temperatures of 423 and 448K are presented. A comparison is made between computed and experimental data on the longevity of specimens with a stress raiser. (4 refs.)

73214 Dynamic crack growth during pop-in fracture in 7075 aluminum alloy. T.Kishi, T.Ohira (Inst. of Interdisciplinary Res., Univ. of Tokyo, Tokyo, Japan).
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.255-63 (April 1983).
The acoustic emission source characterization was carried out to examine the dynamic information about the microfracture processes. The response function of specimens and transducer was obtained experimentally by use of breaking pencil lead as a reference simulated AE source, and the source waves were determined in terms of crack volume-time functions explicitly through a time-domain deconvolution. This method was tested by measuring the acoustic waveforms from pop-in crack growth in 7075-T6 aluminum alloy. The lifetime of each pop-in deduced was about 0.9-2.8 μs, and the crack volumes obtained by this method were consistent with fractographic observations. From these results, the maximum crack velocity was shown to reach about 1000 m/s. (17 refs.)

73215 The interaction of dislocation with Θ'-precipitates in a Al-2.8% Cu-alloy during fatigue tests.
Z. Metallkd. (Germany), vol.74, no.5, p.300-6 (May 1983). In German.
Polycrystalline samples of precipitation hardened Al-2.8% Cu-alloys with Θ'-particles were fatigued in reversed-stress tests in order to examine the plastic deformation behavior. The dislocation hardening mechanisms were studied in the transmission electron microscope. By interaction of dislocations with Θ'-precipitates dislocation networks were formed in the matrix-precipitate interphase boundaries. The dislocations can pass the precipitates by climbing cross slipping of by splitting off a dislocation loop (Orowan loop). These rings ($\mathbf{b}=a/2\langle 011\rangle$) form networks in the interphase boundaries. The interphase plains $(001)_a \| (0010)_{\Theta'}$ of the Θ'-precipitates are the weak spots of the structure, allowing the fatigue cracks to grow in these {001}-planes. (20 refs.)

73216 Determination of fracture-mechanic properties by using the near-field of dynamically loaded cracks. C.Zimmermann (Staatliche Materialprufungsanstalt, Univ. Stuttgart, Stuttgart, Germany).
8. MPA-Seminar. Fracture Behaviour and Nondestructive Testing. Safety of the Pressure Boundary of Light Water Reactors. Materials for Advanced Reactor Systems, Stuttgart, Germany, 14-15 Oct. 1982 (Stuttgart, Germany: Staatliche Materialprufungsanstalt Universitat Stuttgart 1982), p.17/1-11 In German.
The dynamic changes to which the material under crack-causing stress is subjected can be measured by using the stress intensity factor K_I. Research has been projected to investigate the process of crack growth as a function of time and to evaluate K_I. (12 refs.) *G.R.S.*

81.40P Friction, lubrication, and wear

(see also 62.20P Tribology)

73218 Tribological properties of sintered polycrystalline and single-crystal silicon carbide. K.Miyoshi, D.H.Buckley (NASA-Lewis Res. Center, Cleveland, OH, USA), M.Srinivasan.
Am. Ceram. Soc. Bull. (USA), vol.62, no.4, p.494-500 (April 1983).
Tribological studies and X-ray photoelectron spectroscopy analyses were conducted with sintered polycrystalline and single-crystal SiC flat surfaces in sliding contact with an iron pin at temperatures to 1500°C in a vacuum of 30 nPa. The results indicate that there is a significant temperature influence on both the friction properties and the surface chemistry of SiC. The surface revealed a low coefficient of friction. This is believed to be due to the presence of the graphite on the surface. At temperatures of 400° to 600°C, graphite and a copious amount of SiO_2 were observed on the polycrystalline SiC surface in addition to SiC. At 800°C, the amount of the SiO_2 decreased rapidly and the SiC-type silicon and carbon peaks were at a maximum intensity in the XPS spectra. The coefficients of friction were high in the temperature range of 400 to 800°C. SiC-type silicon and carbon peaks were seen on the SiC in addition to very small amount of graphite and SiO_2 at temperatures of 450°C to 800°C. The coefficients of friction were high over the entire temperature range to 800°C. Above 800°C, the concentration of graphite increases rapidly on both polycrystalline and single-crystal SiC surfaces, whereas concentration of the SiC-type silicon and carbon peaks decreases rapidly. The presence of graphite is accompanied by a significant decrease in friction. (33 refs.)

73219 Damage during friction and dislocation structure of gold-platinum solid solutions. N.I.Noskova, V.A.Pavlov, T.P.Bregman, E.A.Soldatova, L.I.Voronova, V.P.Polyakova, E.M.Savitskii (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.55, no.3, p.583-91 (March 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the mechanical strength and plastic properties, and of the friction coefficient. These were combined with the results of electron-microscopic investigations of the fine structure of gold-platinum alloys. The friction coefficient and nature of damage at a friction contact depended on the characteristics of the dislocation structure, formed as a result of deformation, on the degree of localization of strain, and on the nature of damage caused by static stretching of the alloys. (15 refs.) *A.T.*

73220 Antifriction properties of chromium alloys. E.A.Markovskii, I.M.Nedyukha, V.K.Sul'zhenko, N.A.Kachko, O.N.Samgina, O.V.Bakun (Inst. of Casting Problems, Acad. of Sci., Ukrainian SSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.737-41 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.63-8 (Sept. 1982). [received: March 1983]
An investigation was carried out under various specific loads into the effect of temperature on the coefficients of friction and wear intensity of unalloyed chromium, a basic, chromium-6% magnesia alloy, and several alloys produced by adding 0.5% of titanium, zirconium, vanadium, and niobium carbides to the basic alloy. It was found that the decisive factor determining the antifriction properties of chromium alloys at low and moderate temperatures was their level of ductility. It is concluded that alloying with very small amounts (0.5-1 wt.%) of carbides gives the best results, since it both increases the strength and load-carrying capacity of chromium and improves its antifriction properties, without significantly altering its cold-brittleness temperature. (10 refs.)

73221 Tribological properties of cast graphitic-aluminium composites. S.Biswas (Corporate Res. & Dev. Div., Bharat Heavy Electricals Ltd., Hyderabad, India), P.K.Rohatgi.
Tribology Int. (GB), vol.16, no.2, p.89-102 (April 1983).
Some of the tribological properties of cast graphitic-aluminium particulate composite materials are presented. Tests were designed to represent different running conditions, from mixed lubrication to almost dry. Two graphitic aluminium composites, the aluminium alloys on which they were based, and commercial-quality bronze were compared for friction characteristics in these tests. An attempt was made to compare their vibration amplitude characteristics due to stick-slip. Surface features of the mating components after the tests were completed are also presented. It was found that the graphite-aluminium composites perform the best of those tested, in terms of the above-mentioned characteristics, under the most severe running conditions. (16 refs.)

73222 Wear characteristics of composites: effect of fiber orientation. H.-W.Chang.
Wear (Switzerland), vol.85, no.1, p.81-91 (15 Feb. 1983).
Wear characteristics of continuous graphite fiber-epoxy composite were studied on a Falex wear tester by sliding composite rings with various fiber orientations against conforming steel blocks under normal pressure 126 lbf in^{-2} and a surface speed of 0.6 m s^{-1}. The highest wear rate was obtained when the fibers were oriented at 30° from the sliding direction. A good correlation was observed between wear rates and apparent interfacial temperature, and the correlation was qualitatively explained by the energy balance between mechanical energy to break the fibers and thermal energy to the samples. Attempts were also made to correlate viscoelastic properties of the composites with the wear rates by using the apparent interfacial temperatures. (9 refs.)

73223 The role of microstructure in the wear of selected steels. S.F.Wayne, S.L.Rice, K.Minakawa, H.Nowotny (Inst. of Materials Sci., Univ. of Connecticut, Storrs, CT, USA).
Wear (Switzerland), vol.85, no.1, p.93-106 (15 Feb. 1983).
Both AISI 1045 and 2.25Cr-1Mo steels were selected for their capacity to form various phase morphologies at given compositional states. Heat treatment was then performed to produce the desired two-phase (duplex) structure in both materials. The mating counterface to each test material was a 17-4 PH stainless steel in the martensitic condition. Compound impact wear tests were performed at relative transverse sliding velocities of 1 and 10 m s^{-1} with peak nominal contact stress maintained at 69 MPa for various numbers of repetitive load cycles. The formation and characterization of subsurface zones were studied by scanning electron microscopy and energy-dispersive X-ray analysis. Wear debris was inspected by powder X-ray diffraction. The impact wear resistance of AISI 1045 and 2.25 Cr-1Mo steels is dependent on transverse velocity. Variations in velocity lead to 'trade offs' between specimen and counterface 17-4 PH stainless steel wear which is evidenced in weight loss data and correlates with microstructural observations (subsurface zone formation) for each two-phase system. Wear debris analysis confirms the presence of mechanochemical material interaction between specimen and counterface with increasing transformation and oxidation at the higher transverse sliding velocity. (11 refs.)

73224 A study of wear characteristics of different materials. P.Divakar (Mech. Engng. Dept., Regional Engng. Coll., Warangal, India), B.Kotiveerachari, B.G.Krishna Reddy.
Wear (Switzerland), vol.85, no.2, p.151-61 (1 March 1983).
The wear characteristics of different materials including plastics were studied. The variation in mass and linear wear with normal load and speed was determined. An empirical relation was derived for the mass wear of brass sliding against steel in terms of the normal load. The variation in mass and linear wear with material hardness was investigated. Different sliding pairs were studied to assess a minimum wear rate. (8 refs.)

73225 On the wear of aluminium-corundum composites. K.Anand, Kishore (Dept. of Metall., Indian Inst. of Sci., Bangalore, India).
Wear (Switzerland), vol.85, no.2, p.163-9 (1 March 1983).
The effect of corundum particle content on the wear of aluminium was studied. Composites of different corundum contents were tested for their wear characteristics. Hardness and density measurements were made on specimens before and after test. Specimens were examined dy scanning electron microscopy in the as-compacted, sintered and worn states. The wear decreased as the oxide content increased, showing an optimum value at a composition range of 25 wt.% of corundum. The mechanism of reinforcement and its effect on the operative wear mode are discussed. (9 refs.)

73226 Effect of temperature on the cavitation erosion of cast iron. Y.Iwai, T.Okada (Dept. of Mech. Engng., Fukui Univ., Fukui, Japan), F.G.Hammitt.
Wear (Switzerland), vol.85, no.2, p.181-91 (1 March 1983).
Vibratory cavitation erosion tests of gray cast iron, together with tests of tool steel and 316 stainless steel for comparison, were performed at various water temperatures and horn amplitudes under a suppression pressure of 1 bar. The erosion processes for cast iron under the highest temperatures used (200 and 230°F, i.e. 93 and 110°C) are similar to those at room temperature. For each of the materials tested, the maximum weight loss rate increases, shows a peak and then decreases with increasing temperature. However, the maximum damage temperature for cast iron decreases with amplitude, i.e. 200, 170 and 160°F (93, 77 and 71°C) for double-horn amplitudes of 1.0×10^{-3}, 1.38×10^{-3} and 1.78×10^{-3} in (25.4, 35.1 and 45.2 μm). The peak for tool steel and 316 stainless steel occurs at 160°F (71°C) regardless of amplitude. Liquid temperature effects for cast iron erosion were explained by considering the interrelation between corrosive action and mechanical action due to cavitation bubble collapse. (15 refs.)

73227 Subsurface damage during dry sliding wear of Al-Al_3Ni eutectic alloy. R.Salih Yaseen, E.S.Dwarakadasa, A.Razzaq Ismail (Dept. of Production Engng. & Metall., Univ. of Technol., Baghdad, Iraq).
Wear (Switzerland), vol.85, no.2, p.213-21 (1 March 1983).
Cylindrical Al-Al_3Ni eutectic alloy wear pins (10 mm in diameter) were slid against a polished steel surface in a pin-on-disc rotating machine under unlubricated conditions with bearing pressures of 6-60 kPa and a constant sliding speed of 70 m min^{-1}. Metallographic changes in the subsurface region of contact were examined by optical microscopy and microhardness measurements. In the bearing pressure range investigated the alloy exhibited 'mild' wear in two linear regions identified as pure 'oxidative' wear at low bearing pressures and oxidative with superimposed 'metallic' wear at higher bearing pressures. Plastic deformation and fragmentation of the Al_3Ni phase occurred under all bearing pressures. However, in composites prepared by unidirectional solidification containing large Al_3Ni particles fragmentation was insignificant. In all other specimens the size of the fragmented particles in the subsurface region of contact was about 5 μm irrespective of the bearing pressure. (10 refs.)

73228 Morphology of ductile metals eroded by a jet of spherical particles impinging at normal incidence. P.Veerabhadra Rao, S.G.Young, D.H.Buckley (Lewis Res. Center, NASA, Cleveland, OH, USA).
Wear (Switzerland), vol.85, no.2, p.223-37 (1 March 1983).
A detailed morphological study of the erosion of two metals (an aluminum alloy and copper) by normal impact of spherical glass erodent particles was conducted. Damage patterns were studied at several stages of erosion. Scanning electron microscopy and energy-dispersive X-ray spectroscopy were used and surface profile measurements were made. Transformations induced by the erosion process were also studied and the dynamics of the erosion are discussed. The morphology of the damage pattern is a manifestation of the flow pattern of erodent particles and it provides insight into possible mechanisms active at different stages of erosion. The simultaneous appearance of both radial tracks as well as concentric rings is believed to be reported for the first time. Wave crests are observed which contain an accumulation of metallic flakes. From morphological comparisons of the pits over a wide variation in driving gas pressure and time, a well-defined damage and erosion process is evident and preliminary analysis is advanced to explain the formation of the various damage patterns. (32 refs.)

73229 The unlubricated wear of flake graphite cast iron. P.W.Leach, D.W.Borland (Dept. of Metall., Univ. of Melbourne, Parkville, Victoria, Australia).
Wear (Switzerland), vol.85, no.2, p.257-66 (1 March 1983).
The wear behaviour of flake graphite cast iron was correlated with the microstructural parameters of graphite volume fraction and flake size using a pin-on-ring specimen configuration. Pin specimens of cast iron were prepared under carefully controlled melting and casting conditions to provide microstructures with variation in either carbon content or flake size but with the same type A graphite structure and pearlitic matrix. Mild and severe modes of equilibrium wear were identified, the predominant effect of both microstructural parameters being in the severe wear regime. Decrease in flake size and increase in carbon content are detrimental to the wear behaviour resulting in a marked increase in the severe wear rate and a decrease in the mild-to-severe transition load. (20 refs.)

73230 Vibratory cavitation tests at elevated temperature. Yu-Kang Zhou, Xushi Wang, F.G.Hammitt (Dept. of Mech. Engng. & Appl. Mech., Coll. of Engng., East Univ., Ann Arbor, MI, USA).
Wear (Switzerland), vol.85, no.3, p.319-29 (15 March 1983).
Vibratory cavitation erosion curves in tap water are presented for different materials, suppresion pressures, amplitudes and temperatures. At the highest temperatue tested (230°F (110°C)), erosion is still substantial. Damage is found to decrease with increasing temperature above the maximum damage temperature, at least to this temperature (230°F), for all materials tested. Amplitude plays a great role in maximum damage temperature, especially for cast iron. Two distinct maximum mean depth of penetration rate $MDPR_{max}$ points were found for 316 stainless steel and 1018 carbon steel at 230°F. There is a black oxide outer rim on each 1018 carbon steel specimen only at the highest temperature, which is probably due to corrosion effects at the highest temperature. (20 refs.)

73231 Ductility and the abrasive wear of an ultrahigh strength steel. W.M.Garrison, R.A.Garriga (Dept. of Materials Sci. & Mineral Engng., Univ. of California, Berkeley, CA, USA).
Wear (Switzerland), vol.85, no.3, p.347-60 (15 March 1983).
Ploughing of material to either side of the grooves made by abrasive particles and single indenters was observed for both wear and single point cutting. The degree of ploughing decreases as the hardness of the material being tested increases. It is possible to incorporate ploughing into the usual equation for the volume abrasive wear rate by introducing a term $1\text{-}f$, where f is the fraction of a wear groove ploughed to either side of the abrasive particle but not removed from the surface. Although it is possible to relate $1-f$ to hardness through single point scratching experiments, there is evidence that $1-f$ could depend primarily on ductility and not on hardness. As an initial step in exploring the dependence of this ploughing term on the mechanical properties of the abraded material, a simple model of the abrasive wear process is proposed. The model is evaluated in terms of the abrasive wear and tensile properties of a low alloy steel heat treated to hardnesses ranging from 496 to 680 HV. (15 refs.)

73232 Subsurface hardening in erosion-damaged copper as inferred from the dislocation cell structure, and its dependence on particle velocity and angle of impact. D.Kuhlmann-Wilsdorf (Dept. of Materials Sci., Univ. of Virginia, Charlottesville, VA, USA), L.K.Ives.
Wear (Switzerland), vol.85, no.3, p.361-73 (15 March 1983).
Previously published measurements of the cell diameters d of dislocation cells underneath copper surfaces exposed to particle erosion were evaluated in terms of the subsurface stresses τ to which they correspond. These were compared with the elastic stresses expected underneath spherical indenters impacting on the surface with different speeds. The inferred stresses differ markedly from theoretical predictions, not only in regard to the dependence on speed and angle of impact but even in regard to their decay along the z axis, the direction normal to the surface. Instead of τ decreasing as z^{-n} with n continuously rising from 0 at a shallow depth to 2 at large depths, as predicted from elastic theory, the stresses follow a z^{-1} dependence throughout the measured range. All data are satisfactorily explained by the relationship $1/d=(7/z)v^{2/5} \sin \alpha \approx \tau/100$ (using MKS units), where v stands for the velocity of the impacting particles, namely rather irregularly shaped alumina particles 50 μm in diameter, and α is the angle of impact. (11 refs.)

73233 The interaction between two wearing surfaces. I. Copper sliding on Cu-Be and Cu-Be sliding on Cu-Be. M.D.Sexton (Corporate Res. Sci. Labs., Exxon Res. & Engng. Co., Linden, NJ, USA).
Wear (Switzerland), vol.85, no.3, p.375-90 (15 March 1983).
An investigation of the interaction of the two components of a wear system with reference to the physical properties of both components is described. Copper sliding on Cu-Be and Cu-Be sliding on Cu-Be were studied using a ball-on-disc machine, Auger spectroscopy and microhardness measurements. The two systems are found to be qualitatively similar classic examples of severe wear. The wear of a Cu-Be disc sliding under a copper ball is, however, greater than the wear of a Cu-Be disc sliding under a Cu-Be ball. This is attributed to work hardening of the copper ball resulting from an interaction between the two wearing surfaces. Microhardness measurements show that the surface of a Cu-Be ball and a Cu-Be disc are not work hardened during a wear experiment. The surface of a copper ball is work hardened, however, and becomes significantly harder than the wear scar on a Cu-Be ball. As a result the Cu-Be disc wears at a faster rate when sliding under a copper ball than it does when sliding under a Cu-Be ball. (50 refs.)

73234 Effect of simulated body environments on crack propagation in alumina. K.E.Aeberli, R.D.Rawlings (Dept. of Metall. & Materials Sci., Imperial Coll., London, England).
J. Mater. Sci. Lett. (GB), vol.2, no.5, p.215-20 (May 1983).
Double torsion tests were carried out in Ringer's solution and air on plates of alumina used, for femoral ball prostheses. The presence of a liquid environment was found to displace the logarithmic V-K_1 curve (crack velocity against stress intensity factor) to lower K_1 values with respect to air. (16 refs.)

73235 The chemical composition of the T15K6 alloy subjected to diamond-electric polishing with applied vibration. V.V.Dragomir.
Izv. VUZ Mashinostr. (USSR), no.3, p.111-13 (1983). In Russian.
An account is given of an experimental study, with the aid of an electron microscope, of the chemical composition of the T15K6 solid alloy, with the samples subjected to diamond-electric polishing, with applied low-frequency vibrations. The results show that the chemical composition of the T15K6 samples under these conditions changes negligibly; moreover, this treatment increases the strength and working capacity of the cutting part of the instrument. (2 refs.) *Z.F.V.*

73236 Analysis of conditions for powder surface deposition by laser. A.G.Grigor'yants, Yu.N.Redkobordoyi, V.V.Shibaev, A.N.Safonov.
Izv. VUZ Mashinostr. (USSR), no.3, p.155-9 (1983). In Russian.
Employing a solution for the Stefan case, a dependence is derived for the conditions of laser treatment of a cross layer. A comparison of theoretical and experimental data shows that to obtain high-grade coatings, the rate of treatment should be substantially reduced, in which case the lower values correspond to higher powers. This is linked with a reduction of the heat transfer to the substrate material, as well as with a more complete observance of the approximations employed. (6 refs.) *Z.F.V.*

73237 The kinetics of surface craze growth in polycarbonate exposed to normal hydrocarbons. A.Priori, L.Nicolais, A.T.Dibenedetto (Inst. of Materials Sci., Univ. of Connecticut, Storrs, CT, USA).
J. Mater. Sci. (GB), vol.18, no.5, p.1466-72 (May 1983).
A variable radius of curvature strain bending apparatus has been used to investigate the propagation of surface crazes in polycarbonate exposed to a series of normal hydrocarbons from *n*-hexane to *n*-dodecane. In all cases it was found that for crazes growing in a zone free of other crazes, the growth rate was linear at constant temperature, and exponentially dependent upon temperature. An activated-state theory was developed to describe the kinetics of growth in terms of two parameters, B, a dimensionless strain constant which was independent of both the test variables and the crazing agent used, and A′ a characteristic growth rate parameter that varied exponentially with temperature where $A'=G_0 \exp-\Delta E_G/RT$. The rate constant G_0 and the activation energy ΔE_G correlate with the square of the difference between the solubility parameters of the crazing agent and polycarbonate. (11 refs.)

73238 Development of porous antireflective films on borosilicate glasses. A.Iqbal, S.C.Danforth, J.S.Haggerty (Dept. of Materials Sci. & Engng., MIT, Cambridge, MA, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.302-7 (April 1983).
Experiments were conducted to characterize the development of gradient-index antireflective (GIAR) films formed on a phase-separated alkali borosilicate glass. Solution chemistry, secondary-ion mass spectrometry, Auger electron spectroscopy, weight-loss, scanning electron microscopy, and specific surface area analyses were used to evaluate a proposed model for film formation. The results suggest that the film-forming process is more complicated than proposed. For near-optimum heat treatments, the film-formation acid treatment was virtually nonselective; only for much longer than optimum annealing times was selectivity evident. The graded-index films may result from precipitation of dissolved glass. The analyses were complicated by major compositional variations existing in the as-received glass. (19 refs.)

73239 Oxidation of $Hg_{1-x}Cd_xTe$ studied with surface sensitive techniques. P.Morgen, J.A.Silberman, I.Lindau, W.E.Spicer, J.A.Wilson (Dept. of Electrical Engng., Stanford Univ., Stanford, CA, USA).
J. Electron. Mater. (USA), vol.11, no.4, p.597-610 (July 1982). [received: Nov. 1982]
Reports the use of surface sensitive electron spectroscopies to monitor the initial steps of formation of a native oxide on atomically clean cleaved $Hg_{1-x}Cd_xTe$ single crystal surfaces in ultrahigh vacuum (UHV). Here the oxide is formed by oxygen excited by the presence of an operating ion gauge. During the reaction, the composition of the surface region of the substrate was found to change, with a net loss of Hg from the surface. Parallel studies of the compositions of thick anodic oxides using sputter profiling techniques showed only small amounts of Hg in the anodic oxides. (20 refs.)

73240 Thermal oxidation of silicon in the presence of iodine vapor and the properties of iodine oxide layers. V.P.Lebedev, E.E.Pakhomov.
Latv. PSR Zinat. Akad. Vestis Fiz. Teh. Zinat. Ser. (USSR), no.1, p.62-5 (1983). In Russian.
Deals with the substitution of a chlorine-containing component by iodine during the thermal oxidation of silicon with the aim of improving physicochemical and electrophysical parameters of Si-SiO_2. The obtained SiO_2 layers have the density of pores less than 10^2 cm^{-2} for 100 Å oxides. (3 refs.)

73241 Ion etching and its applicability in medicine. Z.W.Kowalski (Inst. Technol. Elektronowej, Politech. Wroclawskiej, Wroclaw, Poland).
Pr. Nauk. Inst. Technol. Elektron. Politech. Wroclaw. Ser. Monogr. (Poland), no.9, p.1-26 (1982). In Polish.
Basic physical effects accompanying ion etching of solids are described. The models of etching of amorphous and crystalline materials are discussed. The changes in the surface topography of solids due to ion etching as well as the possibilities of this process in revealing the structure of materials and modification of their surface are described. The applications of ion etching in medicine are presented, particular attention being given to cytological analyses and modifications of the implant surfaces. (73 refs.)

(inc. stress corrosion cracking; anticorrosion)

73242 **Behaviour of the soft martensitic steel X5 CrNiMo 16 5 containing 2% Mo under corrosion fatigue in aqueous NaCl solutions up to 150°C.** K.G.Schmitt-Thomas, R.Mathis, H.Meisel (Lehrstuhls fur Metall. und Metallkunde, Tech. Univ. Munchen, Munchen, Germany).
Arch. Eisenhuettenwes. (Germany), vol.54, no.3, p.117-22 (March 1983). In German.
The corrosion fatigue behaviour of steel X5 CrNiMo 16 5 containing 2% Mo in aqueous NaCl solutions of different concentration is observed at 20, 80 and 150°C. The corrosion fatigue values are compared with each other and with the behaviour in air, interpretation is made of the experimental results by determination of the general corrosion behaviour and by macro- and microfractographical fracture and crack path assessment. The influence of nonmetallic inclusions on the corrosion fatigue behaviour is discussed. (22 refs.)

73243 **XPS study for the oxidation and the induced segregation at the surface of stainless steels.** A.Mosser, P.Humbert (Univ. Louis Pasteur, Strasbourg, France).
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.260-70 (March 1983). In French.
Interaction of oxygen with two austenitic stainless steel surfaces was investigated by XPS in the low pressure range and at different temperatures. Subsequent vacuum annealings at increasing temperatures were studied too. Similar results are obtained for both samples; they show that the composition of thegrown oxide layer depends on the oxidation temperature. The surface can either be enriched in oxidized iron at 300°C, or in oxidized chromium at 700°C, or in oxidized silicon at 900°C. During vacuum annealings, the less stable oxygen compounds are first reduced and released oxygen forms, with the other elements, the oxides which are still stable at the considered temperature. This phenomenon is accompanied by surface enrichment in these elements. (19 refs.)

73244 **AES studies of the oxides formed on iron-chromium alloys at 400°C.** S.C.Tjong (Dept. of Chem., Case Western Reserve Univ., Cleveland, OH, USA), J.Eldridge, R.W.Hoffman.
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.297-306 (March 1983).
Auger Electron Spectroscopy (AES) has been used to study the compositions and properties of the oxides formed at 400°C on Fe-Cr alloys. The alloys investigated consisted of Cr additions of 3%, 9%, 12% and 18%. It is found that for the Cr additions (Cr=3%), the oxide consists mainly of iron. However, the addition of Cr from 9% up to 18% results in the formation of layered oxides, i.e. Fe_2O_3 exists in the outer oxide/gas interface and $Fe_{3-x}Cr_xO_4$ in the inner region with the predominant chromium oxide next to the substrate. The additions of $Cr \geq 9\%$ to the alloys retard the oxide growth significantly. (16 refs.)

73245 **The mechanism of oxidation of Fe-Ni-Co alloys; the role of Ti and Mo.** I.E.Klein, A.E.Yaniv, J.Sharon (Armament Dev. Authority, Ministry of Defence, Haifa, Israel).
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.351-8 (March 1983).
Specimens of pure Ti and Mo, as well as 250 grade maraging steel, were heat treated in superheated steam at 485°C for 3h. The composition profiles and binding energies were studied, using AES and ESCA techniques. It has been shown that the mechanism of oxide formation is that of caution migration. (11 refs.)

73246 **Study of the superficial sulphurization of brass films supported on steel in relation to metal-rubber adhesion.** J.B.Pelletier, S.Toesca, J.C.Colson (Lab. de Recherches sur la Reactivite des Solides, Dijon, France).
Appl. Surf. Sci. (Netherlands), vol.14, no.3-4, p.375-81 (March 1983). In French.
The growth of thin layers of sulfides on brass plated steel foils has been investigated in relation to metal rubber adhesion. The diffusion profiles of the elements after reaction with hydrogen sulfide have been determined by glow discharge spectrometry, they exhibit initial formation of β-ZnS and subsequent growth of $Cu_{2-x}S$ and CuS when there is no addition element in brass. If a superficial deposit of nickel or cobalt has been achieved on the brass layer, the segregation of the metallic ions is inverted and the additional metal has a diffusion barrier behavior. (11 refs.)

73247 **Modelling approach to corrosion prediction.** C.Edeleanu (Dept. of Metall. & Materials Sci., Univ. of Cambridge, Cambridge, England), J.G.Hines.
Br. Corros. J. (GB), vol.18, no.1, p.6-9 (1983).
The causes of, and penalties arising from, the inability to use our present knowledge to predict corrosion behaviour are outlined. A kinetic model of corrosion is proposed as one method of improving our predictive capabilities and the underlying philosophy is discussed. (5 refs.)

73248 **Analysis of complex polarisation curves [corrosion].** J.G.Hines (Engng. Dept., ICI plc, Winnington, England).
Br. Corros. J. (GB), vol.18, no.1, p.10-14 (1983).
It has long been recognised that analysis of polarisation curves can provide valuable insight into the mechanisms of electrochemical processes provided that the analysis is founded on theoretically based equations such that the coefficients have physical meaning. This approach has however been confined to relatively simple cases where only one or possibly two reactions are involved. An approach has now been developed which permits quantitative analysis of more complex polarisation curves in terms of theoretically based models. The approach is illustrated using the case of stainless steels in acid solutions, but is applicable to other cases. (3 refs.)

73249 **Validification of a computer analysis of potentiodynamic curves [corrosion].** J.H.Cleland, C.Edeleanu (Dept. of Metall. & Materials Sci., Univ. of Cambridge, Cambridge, England).
Br. Corros. J. (GB), vol.18, no.1, p.15-18 (1983).
Prediction of corrosion behaviour from the potentiodynamic polarisation curve is limited by the difficulties met in its quantitative interpretation. To overcome this the potentiodynamic polarisation curve has been modelled and a program called LOOPFIT has been written which can numerically analyse the potentiodynamic polarisation curve. The authors describe the experimental validification of LOOPFIT. (3 refs.)

73250 **Inhibition of iron corrosion in different acid media by N-decylpyridinium derivatives.** A.Frignani (Corrosion Study Centre 'Aldo Dacco', Univ. of Ferrara, Ferrara, Italy), F.Zucchi, C.Monticelli.
Br. Corros. J. (GB), vol.18, no.1, p.19-24 (1983).
Some derivatives of the n-decyl-pyridinium ion (DP) have been tested as iron corrosion inhibitors in sulphuric and hydrochloric acid solutions at 25°C and 70°C. These inhibitors were tested both as bromides and as hydroxides or sulphates. The efficiency of the DP ion can be improved by the introduction of suitable substituents in the 3-position of the aromatic ring. In all the acid solutions tested, the most efficient ion at 25° proved to be the n-decyl-3-hydroxy-pyridinium (D3OP) ion, while at 70°C, the n-decyl-3-carboxypyridinium (D3CP) ion was the most efficient. These derivatives act mainly by physical adsorption between the organic cations and the anions (Cl^- or Br^-) pre-adsorbed at the metal surface of the electrode. But in order to explain all the experimental data other types of interactions have to be considered, such as: Van der Waals attractive forces between the aliphatic chains, interaction of π electrons with the metal surface, and adsorption on to the metal surface. The organic cations studied inhibit mainly the H^+ ion discharge, but when present in higher concentrations they also inhibit the iron dissolution reaction. (38 refs.)

73251 **Corrosion and stress corrosion of arc welds in 18% chromium-2% molybdenum-titanium stabilised stainless steel.** J.Honeycomb, T.G.Gooch (Welding Inst., Cambridge, England).
Br. Corros. J. (GB), vol.18, no.1, p.25-34 (1983).
A study has been made of the effect of welding on the corrosion properties of 18%Cr-2%Mo-titanium stabilised ferritic stainless steel sheet from 2 to 3.5 nm thickness and 9 mm plate. Intercrystalline, pitting and crevice corrosion resistance of welds was evaluated, using immersion and potentiostatic techniques, with stress corrosion behaviour being assessed using transverse weld tensile samples in $MgCl_2$ and $CaCl_2$ solutions. Welding promoted some susceptibility to intercrystalline attack, although all welds passed the Strauss bend test criterion for sensitisation. Resistance to pitting and crevice corrosion in $FeCl_3$ was reduced by welding. No stress corrosion was observed in the parent material, but joints made with nonmatching composition consumables suffered cracking, although susceptibility was less than that associated with austenitic grades of steel. It is concluded that in most environmental situations the loss in corrosion resistance as a result of welding will not be significant. For the highest corrosion resistance, the use of matching composition consumables is preferred. (38 refs.)

73252 **Effect of temperature on the corrosion of 70/30 copper-nickel in sea water.** R.Francis (Grove Labs., BNF Metals Technol., Wantage, England).
Br. Corros. J. (GB), vol.18, no.1, p.35-9 (1983).
Presents the results of experiments to investigate the effect of temperature on the films found on 70/30 copper-nickel. The results show that the potential of 70/30 copper-nickel and 66/30/2/2 copper-nickel explain the poor resistance to impingement attack of this alloy at low temperatures, observed greater than 10°C. At temperatures below 10°C the potential remained more or less constant at about −200 mV (SCE) for the duration of the test. The electropositive shift in potential was associated with an enrichment of iron in the film on the 70/30 copper-nickel alloy. No clear changes in film composition with temperature could be determined for the 66/30/2/2 copper-nickel-iron-manganese alloy. No changes in potential were observed for 90/10 copper-nickel, even after extended testing. (10 refs.)

73253 **Effect of pH on the stress corrosion cracking of α-brass in chlorate solution.** V.K.Gouda (Nat. Res. Centre, Cairo, Egypt), H.A.El-Sayed, G.M.Sherbini.
Br. Corros. J. (GB), vol.18, no.1, p.40-6 (1983).
The stress corrosion cracking (SCC) behaviour of 72/28 brass has been studied in sodium chlorate solutions at ambient temperature over a pH range of 2 to 12, at the open-circuit potential and at controlled potentials, using the slow strain rate technique. A constant strain rate of 1.5×10^{-5} s^{-1} was applied. Under free corrosion conditions, stress corrosion cracking was observed for the specimens tested in the pH range 4-9. Application of cathodic potentials prevented SCC, while application of anodic potentials accelerated SCC in the whole range of pH studied. It was observed that the severity of cracking increased with increase of potential, which was in the range, +200 to +400 mV_H. It was also noticed that, at a fixed applied potential, the SCC severity increased with an increase in pH in the range of pH 2-6, stayed relatively constant up to pH 8 and decreased thereafter. Metallographic inspection revealed that, under open-circuit potential and up to a potential value of $\simeq 200$ mV_H, the mode of cracking was predominantly intergranular, while at potentials >200 mV_H transgranular cracking predominated. The results support the anodic dissolution mechanism of SCC. (24 refs.)

73254 **Evaporation instability and surface oxidation of a solid under irradiation.** M.I.Tribel'skii.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.102-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1127-34 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
A survey is presented of the state of the subject as regards instability resulting in deviation from the initial symmetry when a high-power optical beam interacts with a material. Laser sublimation and thermochemical instability are considered in relation to the growth of the oxide film on a metal heated by a laser beam. (11 refs.)

73255 The relationship of oxide film thickness and composition on titanium to the absorption coefficient on laser irradiation in an oxidizing atmosphere. A.G.Akimov, A.M.Bonch-Bruevich, A.P.Gagarin, V.G.Dorofeev, P.A.Zimin, I.N.Ivanova, M.N.Libenson, V.S.Makin, S.D.Pudkov.

Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.145-51 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1177-85 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).

Studies have been made on the growth kinetics, structure, and optical parameters of oxide films formed on heating titanium in air, by laser beam. It is found that the film thickness determined by optical methods is substantially less than the total depth to which oxygen penetrates into the titanium. Reflection spectra of clean and oxidized titanium specimens have been derived and interpreted; there are marked differences in the kinetics of isothermal and laser oxidation processes. (12 refs.)

73256 An ESCA and Mossbauer study of the oxide layer formed on steel in water containing chromate and chloride ions. W.Meisel, E.Mohs, H.-J.Guttman, P.Gutlich (Inst. fur Anorganische und Analytische Chem., Johannes Gutenberg-Univ., Mainz, Germany).

Corros. Sci. (GB), vol.23, no.5, p.465-71 (1983).

The formation of oxidic layers of steel in chromate solutions was studied by photoelectron and Mossbauer spectroscopy. To simulate more aggressive realistic systems, some chloride ions were added to the solution. The layers formed under these conditions were found to be thicker by an order of magnitude than those formed in the absence of chloride ions. They probably consist of ferric and chromic oxides of the corundum type $(Fe_{1-x}Cr_x)_2O_3$, with the Cr:Fe ratio being depth dependent. The oxide layer is subdivided into small regions behaving superparamagnetically. This heterogeneity of the layer is ascribed to the attack by the chloride ions. The structure of the oxides found differs from the spinel structure reported by other authors who used chloride-free solutions. (22 refs.)

73257 The corrosion inhibition of iron by amines and fatty acids in neutral media. T.Szauer, A.Brandt (Inst. of Inorganic Chem. & Technol., Tech. Univ. of Gdansk, Gdansk, Poland).

Corros. Sci. (GB), vol.23, no.5, p.473-80 (1983).

The inhibitive properties of amine-18C fatty acid salts against the corrosion of iron in 0.5 M Na_2SO_4 have been evaluated. Potentiostatic polarization and resistance measurements in conjunction with corrosion rate determination indicated a substantial difference between the mechanism and efficiency of action of these compounds in neutral and acidic media. On the ground of previous findings the inferior inhibition in neutral media was linked to the tendency of amines and fatty acids to form complexes which did not lead to such effective surface layers as in acidic solutions. (14 refs.)

73258 The corrosion inhibition of iron by amines and fatty acids placed in protective coatings. T.Szauer (Inst. of Inorganic Chem. & Technol., Tech. Univ. of Gdansk, Gdansk, Poland).

Corros. Sci. (GB), vol.23, no.5, p.481-94 (1983).

It has been found that salts of amines and 18C unsaturated acids act in a different manner as corrosion inhibitors in organic coatings, depending on the reaction of the corrosion environment. The salts showed outstanding inhibition activity in the case of the acidic environment. Comparably high inhibitive effects were obtained with these compounds through acidification of the coating material, followed by exposure to a neutral solution. It has also been found that the mode of protection by inhibited coatings can be identified by determining the impedance of coated electrodes as a function of the frequency of the low voltage measuring signal. (42 refs.)

73259 The role of oxide grain boundaries in the development of growth stresses during oxidation. H.E.Evans (Berkeley Nuclear Labs., CEGB, Berkeley, England).

Corros. Sci. (GB), vol.23, no.5, p.495-506 (1983).

A model is described which identifies the oxide growth stresses observed in many systems with the diffusion of anions along oxide grain boundaries and the subsequent formation of an oxide intrusion at the oxide/metal interface. Detailed calculations are made of the elastic stress system within the metal and of the average stress developed in the oxide. For a Pilling-Bedworth ratio greater than unity, the oxide intrusion acts as a linear centre of dilatation generating short-range tensile stresses within the metal and equivalent compressive stresses within the oxide. It is shown that the average value of the oxide stress increases with both the oxide grain size and with the lateral dimensions of the oxide intrusion. (27 refs.)

73260 The corrosion behaviour of AISI 304L stainless steel in 0.1 M HCl at room temperature. I. G.Salvago, G.Fumagalli, D.Sinigaglia (Dept. of Appl. Phys. Chem., Milano Polytech., Milano, Italy).

Corros. Sci. (GB), vol.23, no.5, p.507-14 (1983).

A consideration of the critical potential and the protection potential of localized corrosion is given. From a hypothesis about when a fully developed localized attack can occur a definition of the field of protection potential has been attempted. The potentiostatic method was used to define this field relative to solution heat treated AISI 304L stainless steel in 0.1 M HCl at 20°C, with test times of $\geq$150 h. The results obtained differ significantly from what can be deduced from the potentiodynamic technique, and they confirm the formulated hypothesis and definitions. In the active loop of potentiodynamic curves, the nucleation and development of pitting, together with general corrosion, is documented by SEM. The hypothesis can be advanced that such pitting corrosion is a direct consequence of inhibition phenomena resulting from products formed during overall corrosion. (27 refs.)

73261 The corrosion behavior of AISI 304L stainless steel in 0.1 M HCl at room temperature. II. The effect of cold working. G.Salvago, G.Fumagalli, D.Sinigaglia (Dept. of Appl. Phys. Chem., Milano Polytech., Milano, Italy).

Corros. Sci. (GB), vol.23, no.5, p.515-23 (1983).

For pt.I see ibid., vol.23, no.5, p.507-14 (1983). Describes the results of a study concerning the influence of cold working upon the corrosion behaviour of an AISI 304L in HCl 0.1 M at room temperature. Potentiostatic tests, with test times of $\geq$150 h, followed by SEM observations, revealed that even though cold working lowers the critical pitting potential, it does not impair the susceptibility to localized corrosion. Evidence is provided for (1) pitting activity below the primary passivation potential, and (2) preferential attack on either the austenitic matrix or the martensitic phase, depending upon the corrosion potential below the protection field. It can be hypothesized that the above-mentioned behaviour is a consequence of the formation of corrosion products favoured by the presence of two metallic phases. Such products have inhibiting properties which determine pitting corrosion below the primary passivation potential and, in addition, they hinder the formation of passivity films and facilitate their local destruction. (5 refs.)

73262 Anomalous corrosion of hydrogen-containing ferritic steels in aqueous acid solution. M.Hasegawa (Dept. of Metall. Engng., Waseda Univ., Tokyo, Japan), M.Osawa.

Corrosion (USA), vol.39, no.4, p.115-20 (April 1983).

The effect of dissolved hydrogen in soft iron and ferritic low alloy steel on general corrosion was investigated in acid solutions. Hydrogen charging was carried out in 1 to 28 MPa hydrogen at 723K for 57.6 ks. Weight loss of hydrogen charged ferritic steels was markedly greater than that of hydrogen-free ones, and increased with increasing hydrogen content. Plastic deformation of steels increased the dissolved hydrogen content, and the anomalous corrosion increased with cold working ratio. Anodic polarisation curves of hydrogen charged soft iron and low alloy steel in 0.5 $kmol/m^3$-H_2SO_4 solution exhibited an increase of current density in the passive region in agreement with the corrosion data. This anomalous corrosion was partly recovered by dehydrogenation heating at 573 to 1223K. The anomalous corrosion was dependent on the residual hydrogen content and independent of the structure. It is suggested that the anomalous behavior is caused by activated internal microdefects in steel formed by hydrogen trapping. (16 refs.)

73263 Stress corrosion cracking characterization of 3.5 NiCrMoV low pressure turbine rotor steels in NaOH and NaCl solutions. F.F.Lyle,Jr. (Dept. of Materials Sci., Southwest Res. Inst., San Antonio, TX, USA).

Corrosion (USA), vol.39, no.4, p.120-31 (April 1983).

Describes a research program conducted to determine susceptibility of steels used in low pressure (KLLP) turbine rotors of power plants to stress corrosion cracking (SCC) in LP turbine environments. Slow strain rate SCC tests were conducted on samples from two 3.5 NiCrMoV rotor forgings over a temperature range of 38 to 204 C (100 to 400 F). Environments employed included pure NaOH solutions, 3.5% NaCl, pure water, and mixtures of NaOH and NaCl, Na_2S, Na_2SO_4, or CuO. Supplementary electrochemical data also were generated. Test results indicate that the minimum NaOH concentration required to produce detectable SCC decreases with increasing temperature. Addition of small amounts of NaCl reduced the concentration of NaOH necessary to produce SCC at 157°C (315°F). Pure 3.5% NaCl induced SCC at 121°C (250°F). SCC was not detected in either steel in tests in pure water at 157°C (315°F). (23 refs.)

73264 Sensitization of austenitic stainless steels. II. Commercial purity alloys. R.A.Mulford, E.L.Hall, C.L.Briant (General Electric. Co., Corporate Res. & Dev. Center, Schenectady, NY, USA).

Corrosion (USA), vol.39, no.4, p.132-43 (April 1983).

For pt.I see ibid., vol.38, no.9, p.468 (1982). Presents a study of the effects of nitrogen and molybdenum on the sensitization of commercial purity type 304 and 316 stainless steels. The modified Strauss test (ASTM-A262-E) is used to determine the degree of sensitization of the steels, and Auger spectroscopy and analytical electron microscopy are used to study the chemistry of grain boundaries and the crystallography and chemistry of grain boundary phases. The corrosion data from different alloys are considered in terms of effective chromium content. The corrosion behavior of commercial purity 304 and 316 alloys is found to be inferior to the corresponding high-purity alloys. The Auger data indicates that this is due to the segregation of phosphorus to the grain boundaries. Nitrogen has a beneficial effect on the behavior of type 304 stainless steel, but the improvement due to this element is generally on the behavior of type 304 stainless steel, but the improvement due to this element is generally less than in high-purity alloys. Molybdenum additions strongly improve the corrosion behavior by increasing the amount of chromium depletion necessary for sensitization. (33 refs.)

73265 The anodic dissolution of a Ni-base superalloy. M.A.Cavanaugh (Dept. of Chem. & Phys., Saint Mary's Coll., Notre Dame, IN, USA), J.A.Kargol, J.Nickerson, N.F.Fiore.

Corrosion (USA), vol.39, no.4, p.144-50 (April 1983).

A single phase nickel base superalloy, HASTELLOY Alloy C-276, was anodically polarized in 0.5 N NaCl at 70 C, and the concentrations of metal-ion complexes in solution were determined. Relative dissolution rates of alloying elements were obtained and selectivity coefficients were calculated. The corrosion products that formed at high anodic potentials were identified as $FeCl^{2+}$, Ni^{2+}, $HCrO_4^-$, and MoO_4^{2-}. The pH was observed to decrease and the chloride ion concentration to increase in the electrolyte when diffusion of corrosion products out from an occluded region at the alloy surface was restricted. The increased hydrogen ion concentration in the occluded region was explained by the formation of molybdate and chromate ions as corrosion products. The high corrosion resistance of Alloy C-276 in chloride may be related to the formation of corrosion-inhibiting molybdate ion. (32 refs.)

73266 Electrochemical etching of copper ion implanted H-19 aluminum in aqueous chloride/sulfate solution at 95 C. S.M.Florio, W.M.Moore, G.A.Hutchins, S.E.Summers (Sprague Electric Co., North Adams, MA, USA).

Corrosion (USA), vol.39, no.4, p.151-8 (April 1983).

Electrochemical etching experiments were conducted with Cu ion implanted H-19 Al foil in aqueous $NaCl/Na_2SO_4$ solution at 95°C in an effort to improve the procedure for the surface area enhancement of Al. The concentration of Cu in unimplanted and implanted specimens was determined by electron probe microanalysis. An amorphous passive film on the order of 200 Å thick formed on the Al surface in the 95°C etch solution prior to the electrochemical etch. A model for the etch process in which pits were seen to propagate immediately at flaws in this passive surface was supported by the shape and distribution of etch pits after brief etching. Pits propagated under the surface oxide in crystallographically determined directions in both unimplanted and Cu implanted samples. The presence of ion implanted Cu resulted in a smaller number of more highly developed, deeper pits. Capacitance versus voltage and weight loss measurements of highly etched samples indicated that approximately the same amount of overall Al dissolution occurred in all samples. (27 refs.)

73267 Predictive calculations of volatilities of metals and oxides in steam-containing environments. O.H.Krikorian (Lawrence Livermore Nat. Lab., Livermore, CA, USA).

High Temp.-High Pressures (GB), vol.14, no.4, p.387-97 (1982)., Harwell, Oxon., England, 7-10 Sept. 1981).

Steam-accelerated corrosion of metal alloys and ceramics, and steam volatilization of oxides in general, is a serious problem in a number of energy applications, especially in attempts to extend the conditions for use of materials. Predictive methods are developed here for estimating the bond energies and free energy functions of volatile species having the general formula $MO_x(OH)_y$, in order to extend knowledge of the mechanisms and extent of steam-accelerated volatilization processes. A specific application of the data is illustrated for the case of a proposed process for underground disposal of radioactive waste, where oxides of radionuclides are allowed to equilibrate with 100 atm steam and 10^{-2} atm oxygen at 1000-2000K. Vapor species found to have high volatilities include $Cs_2(OH)_2$, $CsOH$, $AmO_2(OH)_2$, $AmO(OH)_3$, $UO_2(OH)_2$, $NbO(OH)_3$, $PuO_2(OH)_2$, $CeO(OH)_2$, $Ba(OH)_2$, and

$Eu(OH)_3$. Thermodynamic data are tabulated for all possible monomeric species for this specific example. (34 refs.)

73268 Corrosion study of a carbon steel in neutral chloride solutions by impedance techniques. A.Bonnel, F.Dabosi (Lab. de Metall. Phys., Ecole Nat. Superieure de Chimie, Toulouse, France), C.Deslouis, M.Duprat, M.Keddam, B.Tribollet.
J. Electrochem. Soc. (USA), vol.130, no.4, p.753-61 (April 1983).
The electrochemical behavior of a carbon steel in 3% NaCl solution has been investigated using a rotating disk electrode. Both steady-state (diffusional current vs. the disk angular velocity plots) and transient (frequency analysis of the electrohydrodynamical impedance) measurements which specifically sample mass transport phenomena, have been carried out. Oxygen transport takes place not only in the liquid phase but also through a porous layer of corrosion products. From electrochemical impedance measurements, it was found that the corrosion potential the oxygen reduction reaction is under either diffusional or mixed (activation+diffusion) control depending on both the electrode rotation speed and on the hold time at the free corrosion potential. In addition, it was shown that the oxygen consumption occurs not only by electrochemical reduction but also by chemical oxidation of ferrous to ferric ions. Finally, because of the possible occurrence of mixed corrosion control, it is emphasized that the use of the polarization resistance in order to evaluate corrosion rates is not always valid. (16 refs.)

73269 Corrosion inhibition study of a carbon steel in neutral chloride solutions by impedance techniques. F.Dabosi (Lab. de Metall. Phys., Ecole Nat. Superieure de Chimie, Toulouse, France), C.Deslouis, M.Duprat, M.Keddam.
J. Electrochem. Soc. (USA), vol.130, no.4, p.761-6 (April 1983).
The electrochemical behaviour of a carbon steel in 3% NaCl solution containing 10^{-2}M of diamino-1,2-ethane has been investigated using a rotating disk electrode. Both steady-state (current-voltage curves for various disk rotation speeds) and transient (frequency analysis of the electrohydrodynamical and electrochemical impedances) measurements have been carried out. It was concluded that the oxygen reduction process at the corrosion potential was mainly controlled by charge transfer which is at variance with the uninhibited situation. Consequently, polarization resistance measurements can be used in this case to estimate corrosion rates. Regarding the mode of inhibition of diamino-1,2-ethane, the data are consistent with the chelation mechanism proposed for this type of bifunctional compound; it appears that the inhibitive action mainly affects the anodic reaction. (4 refs.)

73270 Observation of nickel inclusions in thermally grown NiO scales. D.Quinn, G.L.Leatherman, R.K.MacCrone, S.R.Shatynski (Dept. of Materials Engng., Rensselaer Polytech. Inst., Troy, NY, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.907-12 (April 1983).
Films of NiO thermally grown at 900°C in various oxygen pressures were examined using magnetic resonance techniques. The NiO films were grown in Ar-O_2 gas mixtures which varied from 0.1 to 1 atm oxygen pressure. Samples were then removed from the nickel substrate and examined using magnetic resonance. These experiments detected discrete cigar or pancake particles of metallic nickel embedded in the NiO scale. Careful examination of these films using optical microscopy also revealed the presence of nickel particles in the NiO external scale. From these results, a model for the oxidation of nickel based upon grain boundary oxidation was developed which incorporates the formation of metallic nickel inclusions in NiO scale. Such results add further insight into the mechanism of oxidation of nickel and reveal further deviation from simple bulk diffusion growth models. (36 refs.)

73271 The cohesive and adhesive strength of ice [on metal substrates]. E.H.Andrews, N.A.Lockington (Dept. of Materials, Queen Mary Coll., London, England).
J. Mater. Sci. (GB), vol.18, no.5, p.1455-65 (May 1983).
The plane-strain fracture-energy test developed by Andrews and Stevenson has been applied to the study of ice adhering to substrates of stainless steel, titanium and anodised aluminium. In most cases the fracture is cohesive through the ice, and therefore yields a cohesive fracture energy (critical energy release rate). The value of this fracture energy, however, is dependent upon the nature of the substrate, stainless steel giving significantly lower values than titanium. The fracture energy is also affected by the rate of formation of the ice and by the rate of testing. Many of these effects can be traced to the influence of the substrate on the air-bubble content of the ice layer. At testing temperatures approaching the melting point of ice, a transition in fracture mode is observed from cohesive to adhesive, and the fracture energy diminishes. The addition of small amounts of sodium fluoride to the water from which the ice is formed, lowers the transition temperature to −5°C, and emphasizes the transition to the adhesive failure mode. (24 refs.)

73272 Surface melting of a medium carbon steel by laser treatment. M.Carbucicchio, G.Meazza (Inst. of Phys., Univ. of Parma, Parma, Italy), G.Palombarini, G.Sambogna.
J. Mater. Sci. (GB), vol.18, no.5, p.1543-8 (May 1983).
A 0.4 wt.%C normalized carbon steel has been graphite-coated and irradiated in air with a cw-CO_2 laser beam at 1.3 kJ cm^{-2} to melt a near-surface layer of material. The solidified and the solid-state transformed regions have been investigated by means of surface Mossbauer spectroscopy, X-ray diffraction, metallography and microhardness measurements. Nature and morphology of the phases have been determined in each region, and their origin discussed in relation to the conditions of the treatment. (13 refs.)

73273 A molecular mechanism for stress corrosion in vitreous silica. T.A.Michalske, S.W.Freiman (Ceramic Dev., Sandia Labs., Albuquerque, NM, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.284-8 (April 1983).
The mechanical strength of most glasses and ceramics decreases with time under static loading in an ambient environment. This strength loss is associated with slow growth of preexisting surface flaws due to stress corrosion by water from the surrounding environment. The authors studied stress corrosion in vitreous silica exposed to water and several nonaqueous environments; environments which enhance stress-corrosion crack growth in silica contain active groups with electron donor sites on one end and proton donor sites at the other. These results suggest a detailed chemical model for the interaction of the environment with mechanically strained bonds in the solid at the tip of a crack. The proposed model for stress-corrosion crack growth also has implications for the long-term strength behavior of a wide variety of brittle materials. (16 refs.)

73274 Crevice corrosion of Ti-0.2% Pd alloy and pure Ti. Sung Tae Ahn, Kwang Bum Kim, Young Ku Yoon (Div. of Materials Sci. & Metall. Engng., Korea Advanced Inst. of Sci. & Technol., Seoul, Korea).
J. Korean Inst. Met., vol.21, no.1, p.25-8 (Jan. 1983). In Korean.
Crevice corrosion properties of Ti-0.2 wt.% Pd alloy and pure Ti in hot 6% NaCl solution were investigated. Pure Ti specimens exhibited severe corrosion, while Ti-0.2% Pd alloy specimens were virtually immune to crevice corrosion in an accelerated test. An electrochemical polarization technique was used to determine the effect of Pd-addition to Ti. It was found that Ti-0.2% Pd alloy retained passivity in an acid solution of the same concentration developed in the crevice. This result indicates that Pd acts as a cathodic depolarizer to shift the potential of Ti in the noble direction. It is therefore concluded that small addition, namely 0.2% of Pd, effectively improves the resistance of Ti to crevice corrosion in a hot brine. (6 refs.)

73275 A fundamental study of laser transformation hardening. S.Kou, D.K.Sun, Y.P.Le (Carnegie-Mellon Univ., Pittsburgh, PA, USA).
Metall. Trans. A (USA), vol.14A, no.4, p.643-53 (April 1983).
A theoretical and experimental study of heat flow and solid-state phase transformations during the laser surface hardening of 1018 steel was conducted. A three-dimensional heat flow model was developed using the finite difference method. The surface heat loss, the temperature dependence of the surface absorptivity, and the temperature dependence of thermal properties were considered. This heat flow model was verified with the analytical solution of Jaeger and was used to provide general heat flow information, based on the assumptions of no surface heat loss, constant surface absorptivity, and constant thermal properties. A continuous-wave CO_2 laser of 15 kW capacity was used in conjunction with a beam integrator to surface harden 1018 steel plates. The beam power and the travel speed of the workpiece were varied, and the onset of surface melting was determined. The configurations of the heat-affected zone observed were compared with those calculated using the heat flow model. The microstructure of the heat-affected zone was explained with the help of the calculated peak temperature, heating, and cooling rates. (27 refs.)

73276 Crack tip oxidation of a superalloy in molten nitrate salt. S.H.Goods (Sandia Nat. Labs., Livermore, CA, USA).
Scr. Metall. (USA), vol.17, no.4, p.533-6 (April 1983).
Examines the influence of a typical nitrate salt composition on crack tip oxidation in Alloy 800 in order to determine if in fact the proposed corrosion phenomena could explain the fatigue crack growth characteristics of the alloy. (5 refs.)

73277 Some considerations on the modelling of oxide-induced fatigue crack closure using solutions for a rigid wedge inside a linear elastic crack. S.Suresh, R.O.Ritchie (Lawrence Berkeley Lab., Univ. of California, Berkeley, CA, USA).
Scr. Metall. (USA), vol.17, no.4, p.575-80 (April 1983).
The significance and limitations of the simple model of a rigid wedge inside a linear elastic crack, used to estimate closure stress intensities resulting from the formation of corrosion deposits during corrosion fatigue, are described. The resultant closure stress intensities predicted by the model are shown to be a strong function of the wedge thickness and its location directly behind the crack tip. Although the wedge thickness can be experimentally estimated by computing the excess oxide thickness from Auger and Secondary Ion Mass Spectroscopy measurements, the oxide film profile in the immediate vicinity of the crack tip is difficult to resolve. Since this near-tip oxide distribution is critical in the estimation of the wedge force, more rigorous calculations of the extent of oxide-induced crack closure are not feasible. (21 refs.)

73278 Formation of the contact zone between a detonation-deposited coating and a basis material. Yu.A.Kharlamov (Voroshilovgrad Machine Construction Inst., USSR).
Sov. Powder Metall. & Met. Ceram. (USA), vol.21, no.9, p.709-11 (Sept. 1982). Translation of: *Poroshk. Metall. (USSR)*, vol.21, no.9, p.31-5 (Sept. 1982). [received: March 1983]
Possible mechanisms of mass transport during the formation of detonation-deposited coatings are examined. The starting materials were standard mechanical mixtures of VK8 (WC+8% Co) powder of particle size not more than 1-2 μm, a mechanical mixture of KKhN-30 (Cr_3C_2-30% Ni) and VSNGN-85 powders of particle size not more than 50 μm, and a copper powder (20-50 μm). (6 refs.)

73279 Pretreatment of galvanized surfaces prior to powder coating. R.D.E.L.Bridger (Waterisation UK Ltd., Croydon, England).
Trans. Inst. Met. Finish. (GB), vol.61, pt.1, p.13-18 (Spring 1983).
Covers the various methods and processes suitable for the pretreatment of galvanized steel surfaces prior to the application of powder coatings, drawing upon results from industrial coating installations as well as those from laboratory testing. It is important to differentiate between the types of zinc coated surfaces and in particular between strip-line galvanized steel sheet and heavy conventional hot dip galvanized steel. The main precleaning processes in use are alkali cleaning/etching and acid etching, the choice being influenced by the method of application and the thickness of the overlying zinc layer. Conversion coatings are necessary to ensure adequate service life and here the choice lies between chromating and phosphating. Accelerated corrosion tests have indicated that certain yellow chromate processes are to be preferred for the treatment of thick galvanized surfaces, whereas chromate, chromate/phosphate and micro-crystalline zinc phosphate processes may all be suitable for use on strip-line galvanized sheet. (no refs.)

73280 The effect of coating alloy composition on the quality of terneplate. S.J.Muckett, M.E.Warwick (Internat. Tin Res. Inst., Greenford, England).
Trans. Inst. Met. Finish. (GB), vol.61, pt.1, p.19-24 (Spring 1983).
The effect of coating alloy composition on the corrosion resistance and porosity of laboratory produced terneplate (cold rolled steel coated with a lead-rich alloy) is assessed. The results indicate that an increase in the tin content of a coating alloy is beneficial to coating quality whereas substitution of antimony for tin is detrimental to coating performance under test. The metallurgy of the bond between the steel substrate and alloy coating is considered, and the likely causes of pores occurring through the coating, which are the sites of subsequent corrosion, are reported. (18 refs.)

73281 The use of electron microscopy in studies of electrolytically coloured anodized aluminium. R.C.Furneaux (Alcan Internat. Ltd., Banbury, England).
Trans. Inst. Met. Finish. (GB), vol.61, pt.1, p.35-40 (Spring 1983).
Deficiencies in the current understanding of electrolytic colouring are identified and considered in terms of film microstructure. Electron optical methods suitable for microscopic study are described and it is indicated how each method has particular applications in elucidating mechanisms operative during colouring and explaining the properties of coloured finishes. Backscattered electron images obtained with the scanning electron microscope clearly reveal the deposit distribution in cross-section within the film. Major differences in distribution have been observed for different black finishes depending on the solution used for electrolytic colouring. Where deposits extend to or near the film surface, they act as preferential pathways for attack leading to premature failure during the acetic acid salt spray test. Transmission electron microscopy reveals the fine structural features of coloured films. Carbon replication and ultramicrotomy allow cross-sections to be studied in detail, while ion beam thinning produces plan sections suitable for examination. Different structures, depending on the relationship between the anodizing and electrolytic colouring voltage, have been observed after colouring in relatively acidic solutions compared with more neutral pH solutions. (20 refs.)

73282 In situ analysis of passive and transpassive films on nickel by modulated UV-visible reflection spectroscopy. N.Hara, K.Sugimoto (Dept. of Metall., Tohoku Univ., Sendai, Japan).
Trans. Jpn. Inst. Met. (Japan), vol.24, no.4, p.236-45 (April 1983).
Modulated reflection spectra have been measured on Ni at passive and transpassive potentials in 0.5 kmol.m^{-3} H_2SO_4 (pH 0.3), 1 kmol.m^{-3} Na_2SO_4 (pH 2.0-12.0), 0.1 kmol.m^{-3} NaOH (pH 13.1), in 1 kmol.m^{-3} NaOH (pH 13.7). By comparing the spectra with those of several reference Ni oxides and oxyhydroxides, constituent substances of passive and transpassive films formed on Ni in these solutions have been identified. It was found that the composition of the films changed remarkably with solution pH and electrode potential: In acid solutions of pH ≤ 4.0, the primary passive film was mainly composed of NiO, and the transpassive film of a nonstoichiometric NI(II) oxide, i.e. NiO_x. The value of x in NiO_x increased with increasing potential. The change in the film composition in neutral solutions having pH between 6.0 and 9.0 was very similar to that in acid solutions, except that a thin layer of λ-NiOOH-2NiO_2 was formed on the surface of NiO_x film. This occurred at transpassivation and oxygen evolution potentials through the anodic oxidation of dissolved Ni^{2+} ions. (38 refs.)

73283 Effect of environmental factors on the magnitude of polarization developed in eutectoid prestressing steels. R.Narayan (Dept. of Metall., Indian Inst. of Technol., Kanpur, India).
Trans. SAEST (India), vol.17, no.4, p.267-77 (Oct.-Dec. 1982). [received: May 1983]
Several service failures of prestressing steels have been attributed to the polarization effects of various concentration cells. The magnitude of such polarization for eutectoid steel in many heat treated conditions under a wide range of environments have been measured over extended periods. The degree of self polarization potentials that could develop under corrosive conditions likely to be met in practice are discussed. It has been estimated that differential oxygen concentration cells and differential stress cells could produce polarization up to 200 mV and 500 mV respectively. Differential chloride concentration could polarize eutectoid steel by 500 mV, whereas coupling with mild steel could polarize up to 700 mV. (4 refs.)

73284 A note on the effect of heat treatment on the magnesium alloy used as galvanic anode. K.Balakrishan, S.Venkatakrishna Iyer, R.Arghode, N.Palaniswamy (Central Electrochem. Res. Inst., Karaikud, India).
Trans. SAEST (India), vol.17, no.4, p.315-19 (Oct.-Dec. 1982). [received: May 1983]
The behaviour of a magnesium quaternary alloy patented in the Central Electrochemical Research Institute, has been examined after heat treatment in an atmosphere of CO_2. The performance of this alloy has been studied and evaluated in respect of self corrosion, anode efficiency and anodic polarisation in 0.01 and 3% sodium chloride solutions. In situ studies and photomicrographic studies have also been carried out, to understand the effect of heat treatment. These studies reveal the fact that while the heat treatment has no beneficial influence on the corrosion resistance of the alloy in 3% sodium chloride solution, it marginally improves the efficiency of the alloy in 0.01% NaCl solution. (13 refs.)

73285 Toluidines as corrosion inhibitors for aluminium-copper alloy in hydrochloric acid. R.B.Patel (Chem. Dept., Government Coll., Daman, India), J.M.Pandya, K.Lal.
Trans. SAEST (India), vol.17, no.4, p.321-4 (Oct.-Dec. 1982). [received: May 1983]
The corrosion of aluminium-copper and its inhibition in hydrochloric acid has been studied. The efficiency of the inhibitor (1.0%) increase as: p-toluidine$<$o-toluidine$<$m-toluidine in different concentrations (0.1N-0.3N) of HCl. The percentage inhibition decreases with increase in the concentration of the acid and time. The influence to current density on the cathodic and anodic polarization of B26S aluminium in 0.1N HCl containing 1.5% inhibitor was also studied. All three inhibitors appear to be effective as mixed inhibitors. (5 refs.)

73286 Parameters of strain-induced corrosion cracking in low alloy steels in a flow of high temperature water. E.Lenz, A.Liebert, B.Stellwag, N.Wieling (Kraftwerk Union AG, Erlangen, Germany).
8. MPA-Seminar. Fracture Behaviour and Nondestructive Testing. Safety of the Pressure Boundary of Light Water Reactors. Materials for Advanced Reactor Systems, Stuttgart, Germany, 14-15 Oct. 1982 (Stuttgart, Germany: Staatliche Materialprufungsanstalt Universitat Stuttgart 1982), p.22/1-15 In German.
The crack corrosion mechanism of low alloy steels: 17 MnMoV64, 20MnMoNi55 and 15NiCuMoNb5 is explained and tests are described aiming at establishing the influence of water acidity and temperature, on cracking of fine-grain steels in a constant high temperature flow of water. The water temperature and its O_2 content were closely controlled. Some suggestions are made concerning possible steps to be taken to counteract the effect of the above parameters on tension-induced corrosion cracking. (11 refs.) *G.R.S.*

81.70 MATERIALS TESTING

(inc. sample preparation for examination, metallographic techniques, ion and electron microprobe techniques, Auger and photoelectron techniques, defectoscopy; for measurement in the mechanics of solids and rheology, see 46.30R)

73287 Report of a preliminary survey of NDT technolgoy with special reference to offshore structures. W.J.Harris (Univ. Coll., London, England).
Br. J. Non-Destr. Test. (GB), vol.25, no.3, p.117-20 (May 1983).
An assessment is made of the UK research and development effort in the fields of monitoring, inspection and nondestructive examination with the emphasis on nondestructive testing instruments and techniques specific to offshore structures. Remote monitoring using vibration analysis and acoustic emission is discussed. NDT techniques, including magnetic particle inspection, ultrasonic measurements and alternating current field measurements are described. Crack characterisation is discussed. Augmentation of NDT research programmes is recommended. (16 refs.)

73288 Inspection of underwater structures by flooded member detection. A.Bennett, D.Brown (R&D Div., British Gas Corp., Killingworth, England).
Br. J. Non-Destr. Test. (GB), vol.25, no.3, p.131-3 (May 1983).
Describes the concept and design of an ultrasonic system, developed by British Gas Corporation, which relies on the detection of sea water in structural members to indicate the presence of a through-wall defect. Results from the field trials using a prototype flooded member detection system show it to be a viable field inspection tool which allows rapid and reliable inspection to be carried out. (no refs.)

73289 In-service nondestructive inspection of heavy loaded structures in particular underwater structures with leakage flux methods. W.Stumm (Magnetische Prufanlagen GmbH, Reutlingen, Germany).
Br. J. Non-Destr. Test. (GB), vol.25, no.3, p.124-6 (May 1983).
The magnetographic technique used for inspecting welds in underwater structures is described. The advantages of the technique in reduced magnetizing power, separation of inspection procedure from evaluation onboard and for dealing with complicated weld geometries are outlined. (no refs.)

73290 Underwater photography of magnetic particle inspection results. G.Mills, C.Priestley, R.Reid, T.Thirlwell (Oceaneering Internat. Services Ltd., Aberdeen, Scotland).
Br. J. Non-Destr. Test. (GB), vol.25, no.3, p.127-9 (May 1983).
A series of trials, onshore and offshore, have been carried out using combinations of contrast and fluorescent magnetic inks and white and ultraviolet light. The conclusions reached so far indicate that the most effective procedure is to use a highly fluorescent magnetic ink illuminated by an electronic flash gun fitted with a filter that passes only ultraviolet light. The image is recorded on an uprated colour film. This flash UV photography has now been successfully used to record real defects in a structure underwater. (no refs.)

73291 An active dummy cell for use in corrosion studies. R.J.Taylor (Materials Res. Labs., Defence Sci. & Technol. Organization, Melbourne, Australia).
Corros. Sci. (GB), vol.23, no.5, p.457-64 (1983).
A dummy cell based on a gold-bonded germanium diode is described. By contrast with the linear current-voltage response of resistive cells, its electrical performance resembles that of an electrode process with Tafel slopes of 60 mV and ∞ respectively. Its behaviour is predictable for both steady state and transient techniques with the advantage over passive dummy cells that the impedance is potential dependent. (18 refs.)

73292 Micro-hardness of non-irradiated uranium dioxide. S.Kim, O.Takagi, N.Obata, T.Kirihara.
J. At. Energy Soc. Jpn. (Japan), vol.25, no.2, p.140-7 (Feb. 1983). In Japanese.
In order to obtain the optimum conditions for micro-hardness measurements of sintered UO_2, two kinds of hardness tests (Vickers and Knoop) were examined with non-irradiated UO_2 for 2.5 and 5 μm in grain size. The hardness values were obtained as a function of the applied load in the load range of $25\sim1000$ g. In the Vickers test, cracks were generated around the periphery of an indentation even at lower load of 50 g, which means the Vickers hardness is not suitable for UO_2 specimens. In the Knoop test, three stages of load dependence were observed for sintered pellet as well as for a single crystal by Bates (1963). Load dependence of Knoop hardness and crack formation were discussed. In the range of applied load around $70\sim100$ g there were plateau region where hardness values were nearly unchanged and did not contain any cracks in the indentation. The plateau region represents a hardness of a specimen. From a comparison between the hardness values of 2.5 μm and those of 5 μm UO_2, it was approved that the degree of sintering controls the hardness in the plateau region. (8 refs.)

73293 Effect of indenter geometry on controlled-surface-flaw fracture toughness. J.J.Petrovic (Los Alamos Nat. Lab., Los Alamos, NM, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.4, p.277-83 (April 1983).
Fracture toughness values obtained using both Knoop and Vickers-indentation-produced controlled surface flaws were compared as a function of indentation load for a well-characterized glass-ceramic material. At the same indentation load, Knoop cracks were larger than Vickers. As-indented K_C values calculated from fracture mechanics expressions for surface flaws were higher for Knoop flaws than Vickers, but both types gave low K_C values due to indentation residual stress effects. Analysis suggested that theoretical formalisms for indentation residual stress effects based on fracture mechanics solutions for a center-loaded penny crack in an infinite medium should apply to both indentation types. K_C values calculated using the residual stress approach were identical for Knoop and Vickers controlled surface flaws when a 'calibration' value for a constant term in the expression for K_C was used for both indentation types. (13 refs.)

73294 **Examination of delayed fracture tests on prestressing steels.** K.Suehiro, E.Yamashita, S.Mizoguchi (Neturen Co. Ltd., Hiratsuka Plant, Hiratsuka, Japan), M.Tanimura, T.Shimada.
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.353, p.222-8 (Feb. 1983). In Japanese.
Three kinds of delayed failure tests have been carried out on induction quenched and tempered SiCr prestressing steel bar and cold drawn prestressing steel wire, under different loading and environmental conditions and using various specimen shapes. (11 refs.)

73295 **Measurement of visual information with texture analysis. II.** M.Hajnal.
Meres & Autom. (Hungary), vol.31, no.3, p.120-7 (1983). In Hungarian.
For pt.I see ibid., vol.30, no.7, p.271-6 (1982). Pt.I contained the requirements for the measurement of textural information, starting from the novel attitude, according to the demands of quality control, summarized the most significant devices and methods and described a new complex texture testing method. The author now demonstrates the applicability of the method through a practical example; classification of high-speed steels on the basis of carbide morphology complemented with fuzzy verification and the phenomenologic examination of the connection between the texture and the material properties. (1 ref.)

73296 **Historical regard to the origin of some partial places in nondestructive testing.** F.Forster.
Mater. Test. (Germany), vol.25, no.5, p.147-52 (May 1983). In German.
Methods are presented for the indication of elastic and inelastic material properties as a function of numerous influencing parameters. The following topics are discussed: introduction of damping capacity into materials research; acoustic emission; crack detection by magnetic leakage flux methods by means of magnetic probes; display of magnetic properties, especially differences in magnetic properties, on a screen; development of impedance plane analysis with eddy current test methods; separation of influencing parameters by impedance plane analysis; eddy current pickup coil test methods with lift-off compensation; electromagnetic quality testing by display on a screen; Forster probe for extremely sensitive measurement of magnetic fields; DC current sorting methods; magnetic point pole method; measurement of low permeabilities; DC magnetography; AC magnetography; a series of test methods integrated in a computer-controlled test block. (42 refs.)

73297 **Economic online inspection of iron castings with X-ray-fluoroscopy and numerically controlled sample handling.** B.Runde.
Mater. Test. (Germany), vol.25, no.5, p.152-4 (May 1983). In German.
The special design of an X-ray inspection system is described, its use for the inspection of cast iron suspension arms. Using a servoelectric handling system, it is possible, to inspect all critical portions of 50 pieces of cast iron suspension arms with a thickness of up to 60 mm in one hour. (no refs.)

73298 **Echo-response of crack-like reflectors in focused ultra-sound-fields. I.** F.Walte, W.Muller.
Mater. Test. (Germany), vol.25, no.5, p.155-8 (May 1983). In German.
It is well known that focusing probes have great advantages in analysing flaws because of their high resolution, but in analyzing flaws one expected that, especially for large flat (crack-like) flaws oriented nearly perpendicular to the surface, an effect would occur called 'mirror-effect', i.e. most of the ultrasonic energy will be deflected mirror-like and therefore missed. The inclination-dependency and the influence of crack-roughness are discussed. (10 refs.)

73299 **Flaw detection on inhomogeneities in dielectrics by radioholography.** A.A.Nadtochii.
Meas. Tech. (USA), vol.25, no.8, p.642-5 (Aug. 1982). Translation of: *Izmer. Tekh. (USSR)*, vol.25, no.8, p.21-3 (Aug. 1982). [received: April 1983]
The scope for using radioholography to measure the deviations in the parameters of a dielectric component from the standard values has been investigated. The results indicate that radioholography enables one to detect deviations in insulating and optically opaque components such as density differences, cracks and other inhomogeneities. The shape of the object can be arbitrary. (2 refs.)

73300 **NDT catches up with composite technology.** S.B.Kulkarni (Morton Thiokol Inc., Brigham City, UT, USA).
Mach. Des. (USA), vol.55, no.9, p.38-45 (21 April 1983).
The technology of nondestructive testing was unprepared for the rapid introduction of composite materials in life-critical applications. Only recently have NDT techniques and equipment been refined sufficiently to cope with the inspection demands of these new materials and applications. But the new inspection methods are costly, and they force users to address the issue of how much NDT is enough. (no refs.)

73301 **Method of analysis of fatigue under complex loading.** A.Le Douaron, T.Lim, R.Lafont (Regie Nat. des Usines Renault, Boulogne, France).
Mem. & Etud. Sci. Rev. Metall. (France), vol.80, no.2, p.105-9 (Feb. 1983). In French.
Presents a materials characterisation example of a series of moterials for the automative industry. The prediction of fatigue fracture of parts is discussed, especially for the cases of a rail, and nonperiodic uniaxial loadings. (no refs.)

73302 **Application of the recording microhardness method to the determination of mechanical material characteristic values of polymers.** M.May, F.Frohlich, P.Grau, W.Grellman (Tech. Hochschule 'Carl Schorlemmer', Leuna-Merseburg, Germany).
Plaste & Kautsch. (Germany), vol.30, no.3, p.149-53 (March 1983). In German.
A new method is described for the continuous measurement of load and indentation during the hardness testing of polymer materials. Analysis of the load line using a special material relationship enables the evaluation of a new hardness number for polymers, differing from the conventional hardness number in that the micro load region is not dependent on the proof load but correlates directly with the inelastic part of the polymer. The new hardness number $L_2VH=2.5\ \sigma_y$ where σ_y is the macroscopic ductile stres. (16 refs.)
A.E.W.

73303 **An experimental study on the relationships between compressibility, fluidity and cohesion of powder solids at small tapping numbers.** M.Yamashiro, Y.Yuasa (Dept. of Planning Technol., Ashikaga Inst. of Technol., Ashikaga, Japan), K.Kawakita.
Powder Technol. (Switzerland), vol.34, no.2, p.225-31 (March-April 1983).
Measurements of cohesion and fluidity are important for industrial control of the properties of powder solids. The compressibility, the fluidity and the cohesion of powder solids are investigated by the method of tapping. In the traditional reports, intervals of N, the tapping number, of 10, 20, 30, 50, 100,... have been widely used. In particular, for powder solids having a small rather than a large particle diameter, the degree of volume reduction C should change significantly with change in tapping number. C decreases gradually if N exceeds a certain value and then does not change when N is increased beyond the tapping number limit. Therefore, C is measured at small intervals of tapping number (1 or 2). A linear relationship between N/C and N is obtained as well as from the traditional results and no unusual phenomenon was observed. It is found, moreover, that Kawakita's formula (1971) relating to compression is applicable. (4 refs.)

73304 **Acoustic emission and its use for the assessment of the strength of ceramic-metal joints.** M.Boniecki, Z.M.Librant, W.W.Wlosinski, W.Mikiel, J.Ranachowski, H.Ryl-Nardzewska.
Szklo & Ceram. (Poland), vol.33, no.2, p.29-34 (July-Aug. 1982). In Polish. [received: April 1983]
The main source of acoustic emissions in ceramics is the propagation of microcracks resulting from any work process. The method enables determination of whether at a given stress level a microcrack is stable. It also makes it possible to investigate the kinetic propagation of cracking. The rate of cracking is a function of the stress coefficient and this relationship is derived mathematically and shown in the form of a curve. The dependence of the number of microscopic cracking processes and the acoustic signals is expressed in the form of an equation and the parameters which affect cracking in ceramics, such as particle size, distance between particles etc. are discussed. An attempt is described to distinguish between acoustic signals resulting from subcritical cracking, macrocracking or surface cracking. The tests were carried out on ceramic cases of diodes, structural details of which are given. A schematic representation of an acoustic detector and test results are presented. The method can be applied as an non-destructive test of ceramic products. (9 refs.) *G.R.S.*

73305 **Statistical modeling of the creep characteristics of structural materials.** A.N.Badaev, E.R.Golubovskii, M.V.Baumshtein, I.P.Bulygin (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.584-9 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.16-20 (May 1982). [received: May 1983]
Using the example of heat-resistance alloys, the authors investigated the feasibility of statistically modeling creep characteristics. An algorithm and program were developed to solve problems of statistically modeling random parameters of an approximate creep equation. The completed work makes it possible to significantly reduce the number and duration of creep tests needed for heat-resistance structural alloys under static thermal and mechanical loads. (10 refs.)

73306 **Prediction of the collapsing pressure of glass fiber-reinforced plastic membranes by the acoustic emission method.** I.S.Guz', A.L.Prokof'ev (Engng. Inst., Acad. of Sci., Kharkov, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.648-54 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.70-5 (May 1982). [received: May 1983]
The authors examined the possibility of using the acoustic emission method for predicting the collapsing pressure of glass fiber-reinforced plastic products subjected to static loading. First they established the dependence of a change in the parameters of the acoustic emission signals when several products were loaded to destruction, and then they kept the load below the value causing destruction, predicted the collapsing load, and in subsequent loading checked the reliability of the prediction. (3 refs.)

73307 **Computation of curves of residual-stress relaxation at normal and elevated temperatures.** N.A.Vishnyakov, G.F.Rudzei.
Strength Mater. (USA), vol.14, no.5, p.687-90 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.101-3 (May 1982). [received: May 1983]
The authors show that the exponential relationship $V=A\sigma_0^n$ (where V is average hourly rate of residual stress relaxation, σ_0 is initial residual stress, and A and n are coefficients dependent on the material, prior history and test conditions) satisfactorily describes the variation in residual stresses in Duralumin specimens with a stress raiser in the interval of tensile loads and thermal exposure parameters investigated. It is thus possible to compute relaxation curves analytically. (3 refs.)

73308 **Equipment for studying structural metallic materials under low-cycle loading conditions with a complex stress state over a wide temperature range.** A.A.Lebedev, F.F.Giginyak, V.V.Storchak, V.V.Bashta, T.N.Mozharovskaya (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.5, p.704-9 (May 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.5, p.115-20 (May 1982). [received: May 1983]
Equipment is described which makes it possible to obtain experimental data for the effect of stress state and temperature on the resistance of structural materials to repeated static alternating loading in the elastoplastic region taking account of stress state and temperature. (8 refs.)

73309 **Instrumentation and methods for scanning Auger microscopy.** M.B.Chamberlain (Sandia Nat. Labs., Albuquerque, NM, USA).
Scanning Electron Microsc. (USA), pt.3, p.937-48 (1982).
The need to determine surface compositions of submicrometer structures in semiconductor devices, metallurgical specimens and a host of other materials has led to many recent advances in the instrumentation and methods for scanning Auger microscopy. Several state-of-the art Auger microprobes employ high emissivity electron sources in the gun assembly and magnetic lenses and coils in the optical column to produce an electron beam with a diameter as small as ≈50 nm. To perform microanalyses of material surfaces with such a small beam without altering the surface composition unacceptably, the placement and efficiency of the electron spectrometer must be optimal; furthermore, the method used to characterize many materials must minimize the dose and/or dose rate. The analytical capabilities of Auger microscopy are being continually improved with the rapid development of ancillary equipment and computer software. (79 refs.)

73310 **Scanning electron microscopy studies on mechanism of rubber tear.** D.K.Setua, S.K.Chakraborty, S.K.De, B.K.Dhindaw (Metall. Engng. Dept., Indian Inst. of Technol., Kharagpur, India).
Scanning Electron Microsc. (USA), pt.3, p.973-80 (1982).
Scanning electron microscopy (SEM) studies of the tearing process of rubber vulcanizates have been made with respect to the following variables: (a) nature of crosslinks (-C-C- and $-S_x$-type); (b) nature of the base polymer (natural rubber and styrene-butadiene rubber); (c) extent of crosslinking; (d) effect of reinforcing filler, HAF carbon black (N 330). Peroxide-cured vulcanizates give rise to stick-slip tear whereas the optimum crosslinked sulfur-cured ones undergo steady tear. In the case of sulfur-cured natural rubber vulcanizates higher crosslink density changes the fracture mode to stick-slip although the tear strength is not influenced much. HAF black-filled vulcanizates undergo brittle fracture. (16 refs.)

73311 Recommended procedure for micro-indentation Vickers hardness test. G.N.Peggs, I.C.Leigh.
Report NPL-MOM-62, Nat. Phys. Lab., Teddington, England (March 1983), 13 pp.
Describes the application of the Vickers microhardness test to metallic specimens at ordinary temperatures. This method is applicable where conventional hardness testing methods, i.e. where the applied load is greater than 9.807 N (1 kgf), are not suitable and where the indentation diagonal length is in the range 20 to 100 μm. 82.20 CHEMICAL KINETICS

73312 Multivariate master equation and its wave solutions. Chen Zhuen-xion, Ho Yu-ping (Inst. of Plasma Phys., Acad. Sinica, Hefei, China).
Acta Phys. Sin. (China), vol.32, no.3, p.285-93 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*
The wave solutions of multivariate master equation for linear reaction system $A \rightleftharpoons X$ have been discussed. Except for the density waves which are obtainable from the usual reaction diffusion equation and multiwave solutions, it is not possible to obtain any fluctuation wave branch. The authors note that, due to the large difference between the spatial scales of chemical reaction and diffusion, it is doubtful to use the multivariate master equation in analysing the critical behaviour of non-linear system. (5 refs.)

73313 Arbitrary order functional sensitivity densities for reaction-diffusion systems. D.K.Dacol, H.Rabitz (Dept. of Chem., Princeton Univ., Princeton, NJ, USA).
J. Chem. Phys. (USA), vol.78, no.8, p.4905-14 (15 April 1983).
The concept of functional sensitivity analysis in the study of diffusion processes in a chemically reacting environment is reviewed and extended to include the notion of arbitrary order functional sensitivity densities. A new perspective on its physical and mathematical basis is offered through a detailed discussion of the motivation behind the formal procedure adopted. The arbitrary order functional sensitivity densities (defined as arbitrary order functional derivatives of a chemical species concentration with respect to the space and time dependent parameters of the system) are shown to obey certain differential equations that can be solved with the help of a Green's function. This Green's function is the inverse of a differential operator that defines an associated linear system in the application of Lyapunov's learized stability theory to (in general nonlinear) reaction-diffusion systems. It is found that the Green's function can be regarded as a concentration response function which allows for an interpretation of the sensitivity densities as generalized response functions. Finally, an illustration of the use of those techniques is provided by applying them to the case of a linear reaction-diffusion system. (17 refs.)

82.30 SPECIFIC CHEMICAL REACTIONS; REACTION MECHANISMS

73314 Solvent effect in the Diels-Alder reaction. L.Pardo, V.Branchadell, A.Oliva, J.Bertran (Dept. de Quimica Fisica, Univ. Autonoma de Barcelona, Barcelona, Spain).
THEOCHEM (Netherlands), vol.10, p.255-60 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).
The solvent effect on the rate constant, regioselectivity and stereoselectivity of the Diels-Alder reaction between 1-hydroxybutadiene and acrolein has been studied theoretically by means of the cavity model. The results obtained are in good agreement with the experimental facts. The fundamental role of charge transfer in the increase of selectivity with the solvent is discussed. (23 refs.)

73315 Quantum state to state reactive probabilities: the $H(D)+Cl_2(v) \rightarrow H(D)Cl(v')+Cl$ reactions. J.M.Alvarino (Dept. de Quimica Fisica, Univ. del Pais Vasco, Bilbao, Spain), A.Lagana'.
THEOCHEM (Netherlands), vol.10, p.271-5 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).
Quantum detailed reactive probabilities for the title reactions have been computed on an optimized LEPS surface. Results are compared with quantum and quasiclassical probabilities reported in the literature. Effects of increasing the reactants' translational energy and changing the mass of the impinging atom are also investigated. (16 refs.)

73316 A semiclassical approach to the dynamics of chemical reactions within the hyperspherical formalism. V.Aquilanti, S.Cavalli, G.Grossi, A.Lagana (Dipartimento di Chimica, Univ. di Perugia, Perugia, Italy).
THEOCHEM (Netherlands), vol.10, p.319-23 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).
Semiclassical techniques are introduced within the hyperspherical coordinate approach, which allows the reduction of many-body problems to the multichannel close coupling formalism in terms of a single (hyper)radial variable. The theory, when applied to collinear chemical reactions, leads to the computation of adiabatic energy levels, and to estimates of nonadiabatic coupling elements. Comparisons are carried out with exact quantum results for the reactions $H+H_2$, $I+HI$, $H+FH$, and their isotopic variants. It is shown that the theory predicts accurately resonance properties and interference effects in reaction probabilities. (7 refs.)

73317 The reaction pathway for the hydration of ketenimine by water dimer. An ab initio study. Minh Tho Nguyen (Dept. of Chem., Univ. of Leuven, Heverlee, Belgium), A.F.Hegarty.
THEOCHEM (Netherlands), vol.10, p.329-32 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).
The reaction pathway for the hydration of the ketenimine $CH_2=C=NH$ by H_2O and $(H_2O)_2$ has been investigated by ab initio methods using STO-3G and 4-31G basis sets, optimized geometries of stationary points being determined by the gradient method. The preferred reaction is with the water dimer which, although it enters the transition state correctly oriented for proton transfer to the β-carbon, does not actually transfer this proton until after the transition state. The reaction is calculated (4-31G) to have an activation barrier of 22 kcal/mole, most of which arises due to the deformation of ketenimine and water dimer. The reaction with water monomer is far less favoured (activation barrier 67 kcal/mole using the same basis set). (11 refs.)

73318 A perturbational molecular orbital analysis of the cycloaddition of 2-carbomethoxy-1,4-benzoquinone to vinylcyclohexene. D.Pitea (Inst. of Phys. Chem., Milano, Italy).
THEOCHEM (Netherlands), vol.10, p.347-52 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).
The application of the intermolecular orbital method to the orientation phenomena in the Diels-Alder reaction of vinylcyclohexene with carbomethoxy-p-benzoquinone is discussed in relation to the frontier orbital approximation and to the limits of the adopted method. (7 refs.)

73319 The cyano group as a model for an electron-withdrawing substituent: two examples. F.Delbecq (Lab. de Chimie Theorique, Univ. de Paris-Sud, Orsay, France).
THEOCHEM (Netherlands), vol.10, p.353-7 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).
The cyano group is largely employed in synthesis for its electron-withdrawing character. But its use in theoretical calculations causes a lot of problems in the study of some reactions, in particular those in which a geometry change occurs or in which the possibility of resonance between several forms exists. Two examples illustrate these difficulties. (11 refs.)

73320 Kinetics of plasmachemical conversion in a silent electrical discharge. J.Rutkowsky, H.Drost, R.Mach (Zentralinst. fur Phys. Chem., Akad. der Wissenschaften, Berlin, Germany).
Beitr. Plasma Phys. (Germany), vol.23, no.2, p.181-91 (1983). In German.
In a silent electrical discharge of barrier type operated at 50 Hz, 10 resp. 20 kV alternating voltages and pressures of $3.32\text{-}9.96\times10^4$ Pa methane was plasmachemically converted to simple hydrocarbons. Ethane and propane were identified as main gaseous products, whereas butane, acetylene, ethylene and propylene occurred in distinct lower concentrations. The decay of methane in dependence on discharge time corresponds up to 1000 s strongly to an exponential function. The formation of alkanes especially ethane follows according to the scheme of a successive reaction; it can be well described kinetically by a 1st order rate equation. (10 refs.)

73321 Pyrolysis products in ion/molecule reactions. II. Amines, thiols, and esters. G.Caldwell, J.E.Bartmess (Dept. of Chem., Indiana Univ., Bloomington, IN, USA).
Int. J. Mass Spectrom. & Ion Phys. (Netherlands), vol.50, no.3, p.235-43 (15 May 1983).
For pt.I see ibid., vol.40, p.279 (1981). The title compounds undergo pyrolytic decomposition on the hot filament of an ionization gauge in an ICR mass spectrometer. The products of pyrolysis are detected by their negative ion/molecule reactions. (22 refs.)

73322 A study of the collision-induced dissociation of $C_2H_5OH_2^+$ using various target gases. P.H.Dawson (Div. of Phys., Nat. Res. Council of Canada, Ottawa, Ontario, Canada).
Int. J. Mass Spectrom. & Ion Phys. (Netherlands), vol.50, no.3, p.287-97 (15 May 1983).
A triple quadrupole mass spectrometer was used to study the collision-induced dissociation of $C_2H_5OH_2^+$ using Ar, Kr, N_2, CH_4, C_2H_6 and C_3H_8 as target gases. The principal fragments were $m/z=29$, 27 and 19. Approximate cross-sections were determined for each decomposition pathway. The products were examined as a function of collision energy up to 75 eV. Threshold energies in the centre-of-mass system were in reasonable agreement with thermochemical values. An extensive survey was made of the fragment ion energy distributions. The $m/z=29$ and 19 fragments, which are easily formed, had relatively narrow distributions which also indicated small scattering angles. At the lower collision energies, the $m/z=29$ ion, which has a higher threshold for its formation, had a very broad distribution indicating a wide range of scattering angles. For the $m/z=29$ and 19 fragments, polyatomic targets gave consistently lower fragment energies than the rare gases. The data also suggest an inverse correlation between scattering angle and collision energy. (13 refs.)

73323 The angular distribution of fragment ions produced from polyatomic ion collisions. P.J.Todd, R.J.Warmack, E.H.McBay (Analytical Chem. Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
Int. J. Mass Spectrom. & Ion Phys. (Netherlands), vol.50, no.3, p.299-313 (15 May 1983).
Energy released to daughter ions from collision-induced dissociation of high energy (~keV) CH_4^+, $CH_3NO_2^+$ and CS_2^+ is measured. Fragmentation mechanics are developed to enable calculation of the angular distribution of fragments due to energy released. Subsequent plots of fragment-ion relative abundance vs. laboratory angle fit published experimental data, even though collisional scatter is presumed negligible. (25 refs.)

73324 Dissociation constants of amino acids in isopropanol+water mixtures. B.P.Dey, S.Dutta, S.C.Lahiri (Dept. of Chem., Univ. of Kalyani, Kalyani, India).
Indian J. Chem. A, vol.21A, no.9, p.886-90 (Sept. 1982). [received: May 1983]
The *pK* values of a number of amino acids have been determined in isopropanol+water mixtures of varying compositions *p*H-metrically. The results show that the changes in pK_1 values are smaller compared to those in the corresponding carboxylic acids, but the changes in pK_2 values are only marginal. It is apparent that the ratio of zwitterions decreases as the [organic solvent] increases. It has been found that the specific solute-solvent interactions are of importance in explaining the change in *pK* values but their nature is not well understood. (17 refs.)

73325 The state-selective reactions of vibrationally excited $CH(X^2\Pi)$ with oxygen and nitrogen. J.A.Duncanson,Jr., W.A.Guillory (Dept. of Chem., Univ. of Utah, Salt Lake City, UT, USA).
J. Chem. Phys. (USA), vol.78, no.8, p.4958-62 (15 April 1983).
The reaction rate constants for the reaction of $CH(X^2\Pi, v''=0, 1)$ with O_2 and N_2 have been measured. CH was produced by IR multiple photon dissociation of methanol and probed by laser induced fluorescence of the $A(0,0)$ (431 nm) and $A(0,1)$ (488 nm) transitions. The second order rate constants are k_{02} $(v''=0)=2.1\times10^{-12}$ cm^3 molecule^{-1} s^{-1}, k_{02} $(v''=1)=4.3\times10^{-12}$ cm^3 molecule^{-1} s^{-1}, k_{N2} $(v''=0)=7.1\times10^{-14}$ cm^{-3} molecule^{-1} s^{-1}, and k_{N2} $(v''=1)=3.0\times10^{-12}$ cm^3 molecule^{-1} s^{-1}. The rate constants for CH $(v''=1)$ are the observed combined rate constants for reaction and vibrational relaxation. (20 refs.)

73326 An analysis of the density dependence of the butane isomerization rate. G.T.Evans (Dept. of Chem., Oregon State Univ., Corvallis, OR, USA).
J. Chem. Phys. (USA), vol.78, no.8, p.4963-8 (15 April 1983).
A Fokker-Planck (FP) and a BGK-like collision operator are used in the analysis of the torsional dynamics of butane. Using previously derived kinetic equations, the authors have determined the torsional correlation time τ as a function of the density (or friction). The inverse of the torsional correlation time, or the isomerization rate, goes to zero at low density, reaches a maximum at an intermediate density, and decreases monotonically for higher densities. Predictions of the FP and BGK-like theories of the isomerization correlation time agree with the classic Chandrasekhar-Kramers result at high to moderate densities, and with stochastic molecular dynamics calculations of Montgomery, Holmgren, and Chandler (1980). (21 refs.)

73327 Orientation dependence in the reaction of Xe* with photodissociation polarized IBr. M.S.de Vries, V.I.Srdanov, C.P.Hanrahan, R.M.Martin (Dept. of Chem., Univ. of California, Santa Barbara, CA, USA).
J. Chem. Phys. (USA), vol.78, no.9, p.5582-9 (1 May 1983).
The reaction of metastable Xe* with IBr to produce XeI* and XeBr* excimers was studied in crossed molecular beams. The IBr beam was rotationally polarized by using laser photodissociation to selectively remove most of the *M* state distribution. The reaction cross section was found to be largest when the Xe* approaches parallel to the plane of rotation of the IBr, and smallest when the Xe* approaches perpendicular to the plane of rotation. Reaction models for excimer formation are discussed, and it is concluded that the observed steric effect results from the anisotropy of the ionic $Xe^+/IBr^-(^2\Pi)$ potential surface, involving the first excited state of IBr^-, which is the intermediate state in the formation of XeI*. (28 refs.)

73328 Theoretical analysis of the quantum contributions to the reactions $H_2(v=1)+H\rightarrow H+H_2(v'=0,1)$ and $H_2(v=1)+D\rightarrow H+HD(v'=0,1)$. R.B.Walker (Theoretical Div., Los Alamos Nat. Lab., Los Alamos, NM, USA), E.F.Hayes.
J. Phys. Chem. (USA), vol.87, no.7, p.1255-63 (31 March 1983).
Detailed quantum-dynamical calculations of the Siegbahn-Liu-Truhlar-Horowitz (SLTH) surface are reported for a rotating linear model (RLM) approximation with and without corrections for bending zero-point energy. These dynamical results predict that there are substantial prethreshold quantum contributions to state-selected cross sections and rate constants for both of the title reactions. However, the mechanisms for these prethreshold quantum effects are not the same. For $H_2(v=1)+H$, a threshold resonance is responsible for the large prethreshold quantum contribution: 65% of the total rate of 300K. For $H_2(v=1)+D$, tunneling is found to be large, leading to a 66% prethreshold quantum contribution at 300K. These large quantum corrections are not large enough to provide an explanation for the previously identified discrepancy between the experimental and classical theoretical rate constants for these reactions. (40 refs.)

73329 Diffusion-controlled reaction of water with glass. R.H.Doremus (Materials Engng. Dept., Rensselaer Polytech. Inst., Troy, NY, USA).
J. Non-Cryst. Solids (Netherlands), vol.55, no.1, p.143-7 (April 1983).
A model in which the diffusion of molecular water controls the rate of reaction of water with glass is considered. As a result of a number of questionable aspects of this model, it is concluded that the ion exchange mechanism is still the best one for the diffusion-controlled reaction of water with alkali silicate glasses. (14 refs.)

73330 Possibility of using recombination reactions and alkali metals to obtain inversion on atomic iodine. T.L.Andreeva, V.I.Babkin, A.I.Maslov, I.I.Sobel'man, E.A.Yukov.
J. Sov. Laser Res. (USA), vol.4, no.1, p.84-91 (Jan.-Feb. 1983).
The possibility of producing a continuous-flow laser operating on an atomic iodine transition is considered. Population inversion is the result of depletion of the lower laser level on account of predominant recombination into iodine molecules in the ground state. Alkali-metal atoms are used to obtain atomic iodine and free radicals without consumption of electric energy. The use of an electric discharge is proposed for the excitation of atomic iodine. The kinetics of the basic chemical reactions is considered and the possibility is demonstrated of obtaining inversion at reasonable working-mixture parameters. The schematic diagram of the laser setup is discussed. (14 refs.)

73331 Charge-transfer interactions with *N*-methylquinolinium ion as electron acceptor. A.S.N.Murthy, A.P.Bhardwaj (Dept. of Chem., Indian Inst. of Technol., New Delhi, India).
Spectrochim. Acta Part A (GB), vol.39A, no.5, p.415-18 (1983).
The charge-transfer interactions of *N*-methylquinolinium ion with aniline and substituted anilines have been investigated by electronic absorption spectroscopy and thermodynamic data determined. The thermodynamic and spectroscopic data has been used to obtain empirical energy parameters from Mulliken's theory. (16 refs.)

73332 An ab initio calculation of the dissociation $C_2H_2(^1\Sigma^+)\rightarrow C_2H(^2\Sigma^+)+H(^2S)$. S.Polezzo (CNR, Milano, Italy), M.Raimondi, M.Simonetta.
Theor. Chim. Acta (Germany), vol.62, no.5, p.477-81 (1983).
The collinear dissociation of acetylene to C_2H and H is studied by a generalized self-consistent procedure. The dissociation energy, the C-H force constant and stretching frequency are computed. (6 refs.)

73333 Determination of the trans-cis-relaxation rate in polymethyne dye molecules. M.V.Bondar, V.I.Bezrodnyi, A.V.Marinchenko, E.A.Tikhonov.
Ukr. Fiz. Zh. (USSR), vol.28, no.4, p.521-5 (April 1983). In Russian.
Nonstationary populations of energy levels in the model of polymethyne dye ПК-693 have been calculated by the Runge-Kutta 4th order method. Dependences of the nonstationary populations vs. the model parameters are analyzed. The constant of trans-cis-relaxation has been determined for polymethyne dye ПК-693 by comparison of the experimental and theoretical data. (7 refs.)

82.35 POLYMER REACTIONS AND POLYMERIZATION

73334 Equilibrium polymerization in two dimensions. M.V.Jaric, K.H.Bennemann (Inst. for Theoretical Phys., Freie Univ. Berlin, Berlin, Germany).
Phys. Lett. A (Netherlands), vol.95A, no.2, p.127-30 (18 April 1983).
A mean-field theory of equilibrium polymerization on a square lattice is presented. A novel feature of the model is the treatment of the whole range of rigidity of polymers (from flexible to stiff) as well as a simultaneous account of both polymer rings and excluded volume. As a result a line of tricritical points is found. (5 refs.)

82.40 CHEMICAL KINETICS AND REACTIONS: SPECIAL REGIMES

73335 A laser method of examining metal ignition kinetics. V.I.Konov, V.G.Ral'chenko, V.N.Tokarev (Lebedev Phys. Inst., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.49-52 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1065-9 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
When a laser acts on a metal in air, the exothermic oxidation at high temperatures may make a contribution to the heating comparable with that from the laser. Quantitative estimates have been made for titanium in air, but no direct measurements have been made of the rate of heat release due to oxidation at the surface. It is desirable to perform such experiments not only because it is necessary to estimate the role of chemical factors in laser working materials, but also if one knows the time course of the heat production from the reaction one can establish the kinetic parameters and thus identify specific features in the laser oxidation. The authors describe a method of examining the ignition kinetics of a metal in response to continuous-wave laser radiation, which involves direct measurement of the heat production by oxidation. (5 refs.)

73336 The induction period of a thermal explosion in a gas between infinite parallel plates. J.Poland (Mech. Engng. Dept., Univ. of Maine, Orono, ME, USA), D.R.Kassoy.
Combust. & Flame (USA), vol.50, no.3, p.259-74 (April 1983).
A study is made of the initiation of gas dynamical processes during the induction period of a high activation energy supercritical thermal explosion in a reactive gas confined between two infinite parallel plates. The detailed development of the density, velocity, temperature and fuel mass fraction fields during the induction period is separated into three phases. During the first phase, occurring on the acoustic time scale of the vessel, conduction-dominated boundary layers generate an acoustic field in a nondissipative interior core region. The second phase, occurring on the conduction time scale of the vessel, is characterised by a pointwise competition between reaction-generated heat release, conduction, and compression. In a supercritical system, $\delta > \delta_{crit}$, the third phase, of extremely limited duration, is dominated by the development of a tiny self-focussing hot spot embedded within a nearly invariant conduction-dominated field filling most of the vessel. (35 refs.)

73337 Flame development in spark-ignition engines. A.Thomas (Cambridge Univ. Engng. Dept., Cambridge, England).
Combust. & Flame (USA), vol.50, no.3, p.305-22 (April 1983).
A theory is developed based on the simple postulation that the rate of burning is the product of flame surface area and laminar burning velocity. The concept of a turbulent burning velocity is thereby not required, and attention is focussed instead on the processes by which flame area increases during combustion. Much is made of the concept of 'flame-stretching' introduced by B. Karlowitz (1953) and of the influence of velocity gradients on this property. Attention is paid to the effect of the complementary component of gas velocity, i.e. that tangential to the flame front. The treatment is independent of assumptions of the thickness of the flame front, and all chemical considerations are incorporated into the property of laminar burning velocity. (20 refs.)

73338 Sensitivity analysis for premixed, laminar, steady state flames. T.P.Coffee, J.M.Heimerl (ARRADCOM, Ballistic Res. Lab., Aberdeen Proving Ground, MD, USA).
Combust. & Flame (USA), vol.50, no.3, p.323-40 (April 1983).
The authors discuss the modelling of premixed, laminar, one-dimensional steady state flames. Such models require a large number of input parameters, the values of which may have large uncertainties. To determine the importance of a given input parameter in evaluating an output function, it is useful to be able to perform a sensitivity analysis. A computer program has been developed to do this for any given flames. The output functions are expressed as Taylor expansions. Both first- and second-order sensitivity coefficients can be computed. As a test case, a sensitivity analysis was carried out for a set of H_2-O_2-N_2 flames. The computed sensitivity coefficients show clearly which mechanisms are important for a given flame. (13 refs.)

73339 Thermal stability/structure relations of some polynitroaliphatic explosives. K.F.Mueller, R.H.Renner, W.H.Gilligan, H.G.Adolph, M.J.Kamlet (Naval Surface Weapons Centre, White Oak Lab., Silver Spring, MD, USA).
Combust. & Flame (USA), vol.50, no.3, p.341-9 (April 1983).
Thermal stability/chemical structure relations were investigated for different classes of energetic compounds containing trinitromethyl, fluorodinitromethyl, and gem-dinitroethyl groups. In the vacuum thermal stability test used to determine the thermal characteristics of the materials, samples are heated to elevated temperatures under vacuum and the amounts of gaseous decomposition products are measured. The following results were obtained: (a) The thermal stabilities of energetic compounds containing trinitromethyl groups are lower than those of materials containing fluorodinitromethyl or gem-dinitroethyl groups if these groups are in a sterically unhindered environment; (b) Energetic materials containing $C(NO_2)_3$-, $FC(NO_2)_2$-, or $CH_3C(NO_2)_2$- groups in an environment which is sterically hindered by neighbouring bulky substituents all have substantially decreased thermal stability compared to unhindered materials. (11 refs.)

73340 The application of silent electric discharges to propagating flames. T.Inomata, S.Okazaki, T.Moriwaki, M.Suzuki (Dept. of Chem., Faculty of Sci. & Technol., Sophia Univ., Tokyo, Japan).
Combust. & Flame (USA), vol.50, no.3, p.361-3 (April 1983).
The authors show it is possible to produce many active species by a silent electric discharge, but, to promote combustion, it is necessary to keep the time interval from production of active species to combustion as short as possible. It is also necessary to ensure that the combustion zone is kept away from the electric field because premature oxidation and field-induced quenching are both counterproductive. (5 refs.)

82.45 ELECTROCHEMISTRY AND ELECTROPHORESIS

(see also 66.10 Ionic conduction in liquids; for electro-osmosis, see 82.65)

73341 Multielectron transfer across the metal electrolyte interface in electrochemical systems. S.Efrima (Dept. of Chem., Ben Gurion Univ. of the Negev, Be'er Sheva, Israel).
Isr. J. Chem. (Israel), vol.22, no.4, p.401-7 (1982).
The theory for the rate of multielectron transfer across the metal electrolyte interface in electrochemical systems is developed. The two-electron case is specifically considered and compared to the one-electron case. The two-electron path may become more important than the parallel one-electron channel under certain well-specified circumstances. (8 refs.)

73342 The electrochemistry of molten lithium chlorate and its possible use with lithium in a battery. S.C.S.Wang, D.N.Bennion (Chem. Engng. Dept., Univ. of California, Los Angeles, CA, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.741-7 (April 1983).
Lithium chlorate, $LiClO_3$, has reported melting points of 127.6° and 129°C. The specific conductance of molten lithium chlorate at 130°C is relatively high compared to common aqueous electrolytic solutions at room temperature. Therefore, lithium chlorate offers the chance to operate a new lithium battery system at a temperature between 30° and 150°C. It was found experimentally that lithium chlorate is stable in the potential range between 3.2 and 4.6 V relative to an Li reference electrode. An Li-Cl_2 secondary battery system was observed to have an open-circuit potential of 3.97 V, making an Li-Cl_2 secondary battery in molten lithium chlorate possible, in principle. A lithium-lithium chlorate primary battery system is also possible. Lithium negative electrode performance was found to be hindered by corrosion and possible runaway reactions with $LiClO_3$. Dendrite formation on charging was observed. The solubility of Li_2O and LiCl in $LiClO_3$ at 145°C is 7.5×10^{-5}d and 1.78×10^{-3} mol/cm^3, respectively. The diffusion coefficients are 1.5×10^{-7} for Li_2O and 3.4×10^{-7} cm^2/sec for LiCl. Platinum appeared to be an inert positive electrode for chlorate, chlorine, or oxygen reactions for runs on the order of several hours. Nickel shows an active-passive behavior which is complex. Nickel appears suitable for use in a primary cell for the cathodic discharge of $LiClO_3$, but it does not appear suitable for a Cl_2 or O_2 electrode. (12 refs.)

73343 Electrolytic recovery of precious metals from dilute aqueous solutions. F.C.Walsh (Chem. Dept., Univ. of Southampton, Southampton, England).
Colloquium on New Tools for Industrial Processes, London, England, 14 April 1983 (London, England: IEE 1983), 9 pp.
Provides a brief profile of some modern electrolytic cell designs, including performance data; to remove and recover metals from dilute industrial process streams. The author discusses case studies of developed designs of: Chemelec cell; bipolar trickle tower reactor; metamatic cyclone cell; Eco-cell; cascade Eco-cell. While the examples given relate to silver, gold and platinum group metals, the cells have also been used to treat a wide variety of the more base metals including, copper, cadmium, nickel, and zinc. 82.50 PHOTOCHEMISTRY AND RADIATION CHEMISTRY

(see also 33.50 Fluorescence, phosphorescence; radiationless transitions)

73344 Dynamics and spatial structure of the absorption at the photochemical stage in insulator destruction. N.M.Bityurin, V.N.Genkin, V.V.Sokolov (Inst. of Appl. Phys., Acad. of Sci., USSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.38-42 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1052-7 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
The photochemical stage in damage to an insulator is considered by reference to polymers. Three-dimensional effects have been identified in the physicochemical processes characteristic of photodestruction. There is a relationship between the distribution of the absorbing products and the mechanisms of the chemical reactions, which provides a new method of examining such processes in solids. For example, the dimensions and position of the localization regions have been established for the photooxidation products from polyvinyl chloride, as well as the regions of elevated concentration of polyene structures. (17 refs.)

73345 Nonresonant laser chemistry in the interaction of intense radiation with matter. A.M.Bonch-Bruevich, M.N.Libenson.
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.6, p.82-94 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.6, p.1104-18 (1982). [received: April 1983] (Proceedings of the Fifth All-Union Conference on Nonresonant Interaction of Optical Radiation with Matter, Leningrad, USSR, 1-4 Dec. 1981).
The heterogeneous laser oxidation of a metal in air is considered as regards the effects of the oxidation on the change in optical parameters and heating rate produced by pulsed or continuous-wave radiation. The thermochemical mechanisms of optical breakdown are considered for transparent condensed media of complex composition, together with the effects of the decomposition of the temperature dependence of the absorption coefficient at high light intensities. (49 refs.)

73346 Electron trapping in alcohol clusters in γ-irradiated alcohol-2,2,4-trimethylpentane-2,2-dimethylbutane glasses at 77K. T.Kimura, K.Yasuda, S.Fukuda, K.Fueki (Dept. of Synthetic Chem., Nagoya Univ., Nagoya, Japan).
Can. J. Chem. (Canada), vol.61, no.3, p.553-7 (March 1983).
An optical absorption study has been made on electrons (e_{alc}^-) trapped in alcohol clusters in γ-irradiated 1-propanol (PrOH)-2,2,4-trimethylpentane (TMP)-2,2-dimethylbutane (DMB), 1-butanol (BuOH)-TMP-DMB, and 1-pentanol (PnOH)-TMP-DMB mixture glasses at 77K. Hitherto electron transfer from the hydrocarbon region into alcohol clusters has been known to be a major process for e_{alc}^- formation in γ-irradiated alcohol-hydrocarbon glasses. However, in PrOH-TMP-DMB, BuOH-TMP-DMB, and PnOH-TMP-DMB, this type of electron transfer was not observed and the e_{alc}^- formation was found to result only from the direct radiolysis of alcohols. In the alcohol concentration range lower than 0.2 electron fraction the yields of e_{alc}^- are less than those expected from the direct radiolysis of alcohols. The average number of alcohol molecules in a cluster in these systems is estimated to be four in the lower alcohol concentration range studied. The position of the absorption maxima for e_{alc}^- in these systems is constant within experimental uncertainties independent of alcohol concentration, which is consistent with the results of a semicontinuum model calculation. (38 refs.)

73347 A new treatment for the interpretation of radical decay in γ-irradiated polyethylene. P.Wuensche (Dept. of Phys., Karl Marx Univ., Leipzig, Germany), J.Limburg, H.-K.Roth.
J. Macromol. Sci. - Phys. (USA), vol.B22, no.2, p.169-83 (1983).
The decay of polymer radicals in γ-irradiated polyethylene as measured by EPR is discussed from the viewpoint of a continuous but not constant distribution over the activation free energy and of the kinetic constants. The possibility of determining this distribution from experimental results alone is shown. In addition, the new treatment enables the authors to obtain more clearly the various temperature regions in which radical decay takes place most rapidly, and this allows a distinction by EPR, for instance, even between several kinds of low-density polyethylene. (10 refs.)

73348 Photolysis of compounds with P-I and As-I bonds. T.L.Andreeva, G.N.Birich, V.N.Sorokin, I.I.Struk, D.N.Suvorov.
J. Sov. Laser Res. (USA), vol.4, no.1, p.31-45 (Jan.-Feb. 1983).
Detailed experimental investigations are reported of the parameters of lasing on the transition $^2P_{1/2} \rightarrow {}^2P_{3/2}$, $\lambda = 1.3$ μm of atomic iodine upon photodissociation of the molecules $(CF_3)_2AsI$ and $(CF_3)_2PI$. The light source was an IFP-5000 flash lamp. The experimental data are used to determine the sequence of the basic reactions that accompany the photolysis of the molecules $(CF_3)_2AsI$ and $(CF_3)_2PI$ and to determine the energy parameters of the generated radiation. (18 refs.)

73349 Photodissociation of the molecules $SiCl_3I$ and SiF_3I. T.L.Andreeva, V.N.Sorokin, I.I.Struk.
J. Sov. Laser Res. (USA), vol.4, no.1, p.46-55 (Jan.-Feb. 1983).
The parameters of lasing based on the transition of atomic iodine and occurring upon photodissociation of the molecules $SiCl_3I$ and SiF_3I are experimentally investigated. The light source employed was a coaxial xenon-filled flash lamp of original construction. The main chemical reactions that accompany the photolysis of the molecules $SiCl_3I$ and Sif_3I and determine the energy characteristics of the generated radiation are analyzed. (10 refs.)

73350 Possibility of lasing in the visible band by molecule photodissociation. T.L.Andreeva.
J. Sov. Laser Res. (USA), vol.4, no.1, p.56-64 (Jan.-Feb. 1983).
The lower excited states of certain diatomic radicals and atoms, transitions from which to the ground state lie in the visible and in the near ultraviolet regions of the spectrum, are analyzed. Possible mechanisms of inversion via photodissociation of the molecules by radiation from a source with a continuous spectrum, having a brightness temperature $T \approx 3 \times 10^4$K, are considered. (27 refs.)

73351 Reactions of excited $I^*(^2P_{1/2})$ and unexcited $I(^2P_{3/2})$ iodine atoms in perfluoroalkyl radicals. T.L.Andreeva, S.V.Kuznetsova, A.I.Maslov, I.I.Sobel'man.
J. Sov. Laser Res. (USA), vol.4, no.1, p.65-84 (Jan.-Feb. 1983).
A method of investigating reactions of excited and unexcited atoms is discussed. It is based on pulsed photolysis of molecules with simultaneous passage of laser radiation through the working medium. The method proposed is used to investigate the reactions that accompany the photolysis of the molecules $RI(CF_3I$, n-C_3F_7I, i-$C_3F_7I)$. The rate constants of the recombination of iodine atoms into I_2 in the presence of RI molecules are calculated for the atoms $I(^2P_{3/2})$ and $I^*(^2P_{1/2})$, as are the recombination constants of the radicals R into R_2 and with the atoms $I^*(^2P_{1/2})$ and $I(^2P_{3/2})$ into the RI molecule. It is shown that the $I(^2P_{3/2})$ atoms are much more active in the recombination into I_2 and RI than the $I^*(^2P_{1/2})$ atoms. The role of the investigated reactions in the kinetics of a photodissociation iodine laser (PDIL) is discussed. The results are compared with the published data. (43 refs.)

73352 Mechanism of hydrogen atom decay in γ-irradiated sulfuric acid glasses. A.Plonka (Max-Planck Inst. fur Strahlenchemie, Mulheim-am-Ruhr, Germany).
Radiat. Phys. & Chem. (GB), vol.21, no.4, p.405-9 (1983).
With the use of an X-band ESR spectrometer coupled with van de Graaff accelerator the decay kinetics of hydrogen atoms produced with apparent radiation yield 2.1-2.8 per 100 eV was followed at 88-113K in 6 M sulfuric acid glasses. The complex decay patterns were adequately described by the second order kinetic equation with time-dependent rate constant of the form $k(t) = Bt^{\alpha-1}$, where the constant α characterizes the variety of hydrogen atom localization sites and the temperature dependence of rate constant is contained in B. In the proposed reaction model the rate limiting step consists in the reorientation of water molecules to form the proper structure for translational movement of hydrogen atoms which are assumed to diffuse very slowly, with time-dependent diffusion coefficient, at low temperatures. The importance of reorientation of water molecules is evidenced by non-Arrhenius behaviour of B in the region of the first peak in the density of vibrational states of solid amorphous water at about 70 cm^{-1}. (18 refs.)

73353 Determination of quantum yield of metal particles to semiconductor in the SnI_2-Ag system. M.T.Kostyshin, V.S.Kostko, V.A.Dan'ko.
Ukr. Fiz. Zh. (USSR), vol.28, no.3, p.455-7 (March 1983). In Russian.
Proposes a method of determining the quantum yield of metallic particles to a semiconductor in a semiconductor-metal system. The quantum yield of Ag in SnI_2 during irradiation of the system with monochromatic light at 450 nm was found to be 8%. (8 refs.) *V.G.P.*

82.50E Photodissociation, photoionization as studied by luminescence and radiationless transitions

73354 On the source of difluorocarbene in IRMPD of dichlorodifluoromethane. D.M.Rayner, S.Kimel, P.A.Hackett (Laser Chem. Group, Div. of Chem., Nat. Res. Council of Canada, Ottawa, Canada).
Chem. Phys. Lett. (Netherlands), vol.96, no.6, p.678-80 (29 April 1983).
The nascent translational energy of difluorocarbene produced in the IRMPD of CF_2Cl_2 has been measured by an optical time-of-flight technique. The energy decreases as the fluence of the infrared laser field increases. This is direct evidence for the secondary photolysis of the CF_2Cl radical in the overall mechanism. (18 refs.)

73355 Rotational excitation in the carbon monoxide product of ketene photodissociation. R.N.Rosenfeld, B.I.Sonobe (Dept. of Chem., Univ. of California, Davis, CA, USA).
J. Am. Chem. Soc. (USA), vol.105, no.6, p.1661-2 (23 March 1983).
Reports the application of an infrared fluorescence method in probing rovibrational energy release to carbon monoxide, formed upon the photodissociation of ketene. The data are in qualitative accord with published data on the CO vibrational energy distribution for this chemistry but additionally demonstrate that rotational energy release is a dominant feature of the reaction dynamics. This result has important bearing on the problem of elucidating the nature of the potential surface for ketene photofragmentation. (17 refs.)

73356 Time-resolved resonance fluorescence studies of $O(^1D_2)$ yields in the photodissociation of O_3 at 248 and 308 nm. G.D.Greenblatt, J.R.Wiesenfeld (Dept. of Chem., Cornell Univ., Ithaca, NY, USA).
J. Chem. Phys. (USA), vol.78, no.8, p.4924-8 (15 April 1983).
The yield of electronically excited oxygen atoms $O(^1D_2)$ following excimer laser photolysis of ozone at 248 and 308 nm was directly measured using time-resolved resonance fluorescence emission at ≈130 nm. The result obtained at 248 nm is in good agreement with a previous resonance fluorescence measurement in which the yield of ground-state $O(^3P_J)$ was determined in the presence of gases which either quenched or reacted with $O(^1D_2)$. The relative yield determined at 308 nm 0.79 ± 0.02 is the first such determination in the region of weak Hartley band absorption near the thermochemical threshold for production of $O(^1D_2) + O_2(a^1\Delta_g)$. When taken in conjunction with the previously measured relative yields of $O(^1D_2)$ at this wavelength, this result suggests that the yield of electronically excited oxygen atoms at 300 nm is 0.96 ± 0.02. Orientation dependence in the reaction of Xe* with photodissociation polarized IBr .... See Entry 73327

82.60 CHEMICAL THERMODYNAMICS

(see also 05.70 Thermodynamics)

73357 Study of correlation effects in the calculation of heats of reactions. J.Breulet, J.Lievin (Service de Chimie Phys. Moleculaire, Univ. Libre de Bruxelles, Bruxelles, Belgium).

THEOCHEM (Netherlands), vol.10, p.341-5 (May 1983). (XIII Congress of Theoretical Chemists of Latin Expression, Alghero, Sardinia, 5-8 Oct. 1982).

A simplified method of correlation energy calculation has been recently proposed. This method, which was shown to give good reaction heats where HF calculation fails (dissociations) is tested here in the calculation of reaction heats for which the HF approximation gives good results. (4 refs.)

73358 Standard free energy of formation of iron iodide. A.Khandkar, V.B.Tare, J.B.Wagner,Jr. (Center for Solid State Sci., Arizona State Univ., Tempe, AZ, USA).

J. Electrochem. Soc. (USA), vol.130, no.4, p.880-2 (April 1983).

By using silver iodide as a solid electrolyte it is possible to formulate a galvanic cell Ag|AgI|Fe-FeI_2 to determine the free energy of formation of iron iodide. The thermodynamic stability of FeI_2 is not known precisely, but it appears to be less stable than AgI. Thus if the cell satisfies the criteria for reversability, the open-circut EMF is related to the free energy change of the cell reaction by $\Delta G_{cell}=-nE\mathrm{F}=2\Delta G°_{AgI}-\Delta G°_{FeI2}$, where n is number of electrons transferred during the cell reaction, E the EMF in volts, and F the Faraday constant. The overall cell reaction is $2Ag+FeI_2=2AgI+Fe$. The standard free energy of formation of AgI is known and hence it is possible to estimate the standard free energy of formation of iron iodide by measuring the open-circuit EMF of the above cell as a function of temperature. (10 refs.)

73359 Thermodynamic properties of aqueous solutions of the alkali metal chlorides to 250°C. H.F.Holmes, R.E.Mesmer (Chem. Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).

J. Phys. Chem. (USA), vol.87, no.7, p.1242-55 (31 March 1983).

Osmotic coefficients of LiCl(aq), KCl(aq), and CsCl(aq) have been determined, at 225 and 250°C, by isopiestic comparison with NaCl(aq). Equilibrium molalities ranged up to 8 mol kg^{-1}. Isothermal osmotic data can be precisely described by the ion interaction model of Pitzer (1973). The osmotic, and activity, coefficients continue to decrease with increasing temperature with LiCl(aq) retaining a measure of individuality when compared to the other alkali metal chlorides. The authors' present results have been compared and combined with previously reported thermodynamic data (isopiestic and vapour pressure measurements, electrochemical cell potentials, freezing temperature determinations, enthalpies of solution and dilution, and heat capacities) within the framework of the ion interaction model. The resulting set of equations provides a thermodynamic description, essentially within the accuracy of the reported experimental results, of LiCl(aq), KCl(aq), and CsCl(aq) as a function of temperature (from 0 to 250°C) and molality (up to about 6 mol kg^{-1}). The ion interaction parameter $\beta^{(0)}$ was in the order $LiCl>NaCl>KCl>CsCl$ at all temperatures. The same trend was observed for the excess thermodynamic properties ϕ, γ, and ${}^{\phi}L$. Contributions of the short-range interactions to the activity coefficient ($\ln \gamma\text{-}f^{\gamma}$) are linearly related to the reciprocal radius of the cation. Excess free energy data for the alkali metal chlorides to 250°C can be modeled surprisingly well with a single parameter—the hard-core diameter—using the theoretical form of the ion interaction model. (77 refs.)

73360 Heterogeneous reactions and chemical transport of molybdenum with halogens and oxygen under steady state conditions of incandescent lamps. G.Dittmer, U.Niemann (Philips GmbH Forschungslab. Aachen, Aachen, Germany).

Mater. Res. Bull. (USA), vol.18, no.3, p.355-69 (March 1983).

Thermodynamic data of molybdenum chlorides and oxychlorides have been derived from transport measurements. A critical revision of literature data and an application of theoretical estime enable the authors to present a complete set of data for gaseous molybdenum halides, oxyhalides and oxides and for a selected number of liquid and solid compounds. 82.65 SURFACE PROCESSES

73361 Study of surface poisoning and regenerating on $LaNi_5$ by sulphides. Yu Shing-nan, zhang Ching-Zhe, Xie Kan, Kang Gin, Lin-Zhang-da (Inst. of Phys., Acad. Sinica, Beijing, China).

Acta Phys. Sin. (China), vol.32, no.3, p.360-5 (March 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)*

This article is a brief summary of the authors' study on poisoning and regenerating at the surface of $LaNi_5$ by impurities, which are H_2S, SO_2 and CS_2 contained in the hydrogen used. The AES, XPS analyses show that the feature of the poisoning for three sulfides are different: $LaNi_5$ poisoned by H_2S produces the surface compounds, such as La_2S_3 and NiS. The chemisorption and physisorption occurred due to SO_2 and CS_2 poisoning respectively. In addition, surface catalytic property of active nickel on $LaNi_5$ can be shown by evaluation of the changes in the intensity of nickel peak in the Ni($2p_{3/2}$) spectrum. Pure hydrogen cycle method is effective for regeneration of $LaNi_5$ poisoned by SO_2 and CS_2, but this is not true for H_2S-poisoned samples. These results are very useful in explaining the mechanisms of rare earth intermetallic hydrides surface poisoning and regenerating. (4 refs.)

73362 Enhanced char reactivity via a tailored pore structure. G.A.Simons (Phys. Sci. Inc., Andover, MA, USA).

Combust. & Flame (USA), vol.50, no.3, p.275-85 (April 1983).

A single-particle char oxidation model is summarised and utilised to illuminate the role of the pore structure in char oxidation. The model describes the pore structure, mass transport, and the heterogeneous chemistry which occur during the oxidation of porous coal char. The pore structure is depicted as a collection of pore trees, with a continuous size distribution and branching sequence. Oxygen diffuses into the pore tree and consumes carbon from the walls of the pores. The basic heterogeneous rate constants have been inferred from existing laboratory data on nonporous carbon, and the oxidation model is validated with data on porous carbon char. The influence of the physical properties of char on its reactivity to oxygen have been quantitatively assessed. (29 refs.)

73363 Statistical rates for reactions on a heterogeneous surface. S.D.Prasad, L.K.Doraiswamy (Nat. Chem. Lab., Pune, India).

Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.31-6 (6 May 1983).

Using the random patch model, kinetic expressions are derived for the pressure dependence of first- and second-order surface reactions. Employing first- and second-order Stieltjes transforms and a Mellin transform, explicit expressions are derived for the rates as functions of pressure and the parameters characterizing the site energy distribution. It is shown that the rates reflect the nature of the four distributions studied. (13 refs.)

73364 Osmotic and activity coefficients of some pyridine complexes with halogenoacetic acids in benzene at 25°C. Z.Dega-Szafran, M.Szafran (Dept. of Chem., A. Mickiewicz Univ., Poznan, Poland).

J. Mol. Liq. (Netherlands), vol.25, no.2, p.109-13 (April 1983).

Osmotic coefficients measured by vapour pressure osmometry are reported for benzene solutions of complexes of pyridine with trifluoracetic, dichloroacetic and chloroacetic acids at 25°C. Solute activities decrease with increasing concentration due to formation of self-associates. It is suggested that dipole-dipole interactions contribute substantially to the stability of the associates. (5 refs.)

73365 Diffusional boundary layer resistance for membrane transport. M.P.Bohrer (Bell Labs., Murray Hill, NJ, USA).

Ind. & Eng. Chem., Fundam. (USA), vol.22, no.1, p.72-8 (Feb. 1983).

Diffusional fluxes across well-characterized membranes were measured for a variety of solutes in a stirred diffusion cell. The results were analyzed in terms of a diffusional boundary layer model based on transport through a membrane containing a uniform array of circular pores. Diffusional boundary layer resistances (R_b) were calculated from the measured fluxes and compared to values obtained using a polarographic technique and to values determined indirectly from the stirring speed dependence of the overall mass transfer resistance. The measured values of R_b were found to be strongly influenced by the membrane porosity, R_b for the lowest porosity (1.7%) membrane being twofold greater than R_b for membranes with porosities of 6.2 or 19.9%. (20 refs.)

73366 On models of interactive dynamical processes at surfaces. U.Landman (School of Phys., Georgia Inst. of Technol., Atlanta, GA, USA).

Isr. J. Chem. (Israel), vol.22, no.4, p.339-59 (1982).

One of the major objectives of surface science is the understanding of the fundamental processes involved in chemical reactions catalyzed by solid surfaces. A catalyzed surface reaction may conveniently be described by a sequence of elementary kinetic steps such as adsorption (which may proceed via stages involving precursor states, physisorption etc.); diffusion (on the surface and in certain cases through the bulk); reaction (dissociation, association, rearrangement etc.) and desorption. The traditional thermochemical analysis of reactions involving the balance of heats of the above distinct processes, such as heats of adsorption, desorption, dissociation and bond formation, provides criteria for the occurrence of certain reaction paths. However, such analysis, while determining the direction of the process in the reactants-products space, does not provide detailed information about the reaction rates and the fundamental microscopic processes which govern them. The employment of specific catalytic agents in a chemical reaction provides the means for modifying reaction paths and rates. In addition, through the use of the proper catalyst a particular reaction channel, selected from the manifold of thermodynamically allowed ones, may be enhanced. In order to enable one to choose specific catalysts with the objective of optimizing the yield of a desired reaction product it is necessary to develop an understanding of the microscopic interaction processes and to identify the physical parameters of the catalytic system (catalyst, reactants, and ambient conditions) which govern the outcome and rate of the reaction. (132 refs.)

73367 Studies of structure and dynamics in heterogeneous reactions. S.L.Bernasek (Dept. of Chem., Princeton Univ., Princeton, NJ, USA).

Isr. J. Chem. (Israel), vol.22, no.4, p.395-400 (1982).

The combination of methods from surface chemical physics with methods from studies of molecular reaction dynamics can provide a detailed understanding of the dynamics of heterogeneous reactions. Examples from work in the author's laboratory are used to illustrate this approach to the study of gas-solid reactions. (20 refs.)

73368 Oxygen permeable membrane for oxygen enriched combustion. S.Asakawa, Y.Saito, M.Kawahito, Y.Ito, S.Tsuchiya (Matsushita Res. Inst., Tokyo Inc., Tokyo, Japan), K.Sugata.

Natl. Tech. Rep. (Japan), vol.29, no.1, p.93-101 (Feb. 1983). In Japanese.

An oxygen enriched air production system using gas separation membranes has been developed to be used for fuel combustion systems. High oxygen permeable copolymers, including three dimensional structure have been synthesized through condensation of polyvinylphenol with some, α, ω-bis (diethylamino) polydimethylsiloxanes. The experimental results showed that the oxygen permeability through the copolymer varies as a function of the dimethylsiloxane content of the copolymers. Such composition dependence of the oxygen permeability was explained on the basis of polymer constitution. The copolymers are soluble in most common organic solvents and uniform, defect-free membranes as thin as 1000 Å have been formed by spreading solutions of the copolymer on water. Composite membranes fabricated by applying the membranes to porous support materials were used for practical gas separation and 30% oxygen enriched air was produced from ambient air. A new type oxygen enriched combustion system, which is more efficient for energy saving, has been developed by utilizing oxygen enriched air thus produced. (15 refs.)

73369 Adsorption and reactions of CO, NO, H_2 and O_2 on group VIII metal surfaces. B.E.Nieuwenhuys (Gorlaeus Lab., Rijksuniv. Leiden, Leiden, Netherlands).

Surf. Sci. (Netherlands), vol.126, no.1-3, p.307-36 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).

The adsorption of CO, NO, H_2, O_2, H_2O, CO_2 and N_2 is discussed in relation to the activity and selectivity of the various Group VIII metals in reactions of oxygen with hydrogen and carbon monoxide, nitric oxide with carbon monoxide and hydrogen, and carbon monoxide with hydrogen. (111 refs.)

73370 The reaction of sputtered FeTi with UHV residual gas studied by XPS. M.Polak, M.Hefetz, M.H.Mintz, M.P.Dariel (Ben-Gurion Univ. of the Negev, Beer Sheva, Israel).
Surf. Sci. (Netherlands), vol.126, no.1-3, p.739-44 (March 1983). (ECOSS-5. Proceedings of the Fifth European Conference on Surface Science, Gent, Belgium, 24-27 Aug. 1982).
X-ray photoelectron spectroscopy (XPS) studies of polycrystalline FeTi surfaces under UHV conditions (2×10^{-10} Torr) revealed the presence of selective interactions between the titanium atoms at the ion-sputtered surface and H_2O molecules from the residual gas. Titanium oxide (TiO) becomes, during the exposure, the dominant surface species as inferred from the Ti($2p_{3/2}$) and O(1s) chemical shifts. The Fe(2p) spectrum characteristic of metallic iron hardly changed during the entire exposure. Sputter-induced structural defects at the FeTi surfaces are supposed to accelerate TiO nucleation. (12 refs.)

73371 Influence of aluminum adatoms on the germanium oxidation process. A.D.Katnani, P.Perfetti, Te-Xiu Zhao, G.Margaritondo (Dept. of Phys., Univ. of Wisconsin, Madison, WI, USA).
Fifteenth Annual Synchrotron Radiation Users Group Conference (papers in summary form only received), Stoughton, WI, USA, 18-19 Oct. 1982 (Stoughton, WI, USA: Synchrotron Radiat. Center 1982), p.28
Ultrathin Al overlayers (0.4-2 Å) dramatically increase the oxidation rate of Ge(111) surfaces. The resulting initial chemisorption phase does not correspond to any of the known oxides of Ge or Al. A study of photoemission spectra of the core levels and of the valence band taken with synchrotron radiation gives information on the nature of this new phase. In particular, low oxygen exposures shift in energy the Al2p level while they do not affect the Ge3d level. However, neither the Al2p core-level spectra nor the valence-state spectra correspond to those of oxidized aluminum. For example, the chemical shifts of the Al2p level in oxidized Al and in the new phase are different by about 1.5 eV. Possible models will be discussed for the new phase which is likely to provide a stable interface between Ge and germanium dioxide. (no refs.)

(for flow behaviour, see 47.55K)

73372 Small-angle neutron scattering from an oil-in-water microemulsion as a function of temperature. L.J.Magid (Dept. of Chem., Univ. of Tennessee, Knoxville, TN, USA), R.Triolo, R.M.Jones, J.S.Johnson,Jr..
Chem. Phys. Lett. (Netherlands), vol.96, no.6, p.669-73 (29 April 1983).
A multicomponent oil-in-water microemulsion containing CTAB ($C_{16}H_{33}NMe_3Br$), *n*-octane, 1-butanol, NaBr, and D_2O has been studied by small-angle neutron scattering at several temperatures. The size of the microemulsion droplets was found to be independent of temperature. Correlation lengths for the critical concentration fluctuations agree with those determined earlier by light scattering. (4 refs.)

73373 The friction coefficient in deswelling gels. A.M.Hecht (Lab. de Spectroscopie Optique, Univ. de Savoie, Chambery, France), E.Geissler.
Polym. Commun. (GB), vol.24, no.4, p.98-101 (April 1983).
Measurement of the swelling pressure of a polymer gel in uniaxial symmetry gives direct access to the longitudinal osmotic modulus M_{os}. For polyacrylamide-water gel, at concentrations $c<0.2$ g cm^{-3} such observations are in good agreement with a scaling model of the gel in which account is taken of the shear elasticity. The collective diffusion coefficient $D\text{-}M_{os}/f$, where f is the friction coefficient, has previously been found by Bastide and Candau (1982) to deviate strongly from the scaling prediction upon deswelling, on account of the different behaviours of the shear and the osmotic contributions to M_{os}. It is shown, from measurements of the uniaxial deswelling rates of the gels as a function of applied pressure, that f also deviates from scaling behaviour, for small variations in concentration, f varies as $c^{1.5}$, as predicted by scaling considerations, while for larger variations, f varies approximately as $c^{1.25}$. (19 refs.)

73374 Equilibrium aggregation in a moderately concentrated finely dispersed system. Yu.A.Buevich (A.M. Gor'kii Ural State Univ., Sverdlovsk, USSR).
J. Eng. Phys. (USA), vol.43, no.2, p.913-19 (Aug. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.2, p.280-7 (Aug. 1982). [received: April 1983]
The equilibrium properties of dispersed small interacting particles capable of reversible aggregation are investigated. (12 refs.)

73375 Effect of sedimentation on Taylor diffusion. C.Van den Broeck, E.Dekempeneer (Vrije Univ. Brussel, Brussel, Belgium).
Phys. Rev. A (USA), vol.27, no.5, p.2727-30 (May 1983).
The authors calculate the effective longitudinal diffusion coefficient K of a Brownian particle suspended in a fluid of different specific weight (difference $\Delta\rho$), in laminar flow between two plane parallel plates (at a distance L). In the case of spherical particles (radius a), one finds a fast decrease of K due to sedimentation for values of a larger than the value a_M for which K reaches a maximum. Typically a_M is of the order of 10^{-5} cm. Its precise value depends on $\Delta\rho$, L, and the characteristics of the flow (Poiseuille or linear shear). The possible experimental verification is discussed. (6 refs.)

73376 Influence of thermal treatments on the structure and stability of gelatin gels. M.Djabourov, P.Papon (Lab. de Dispositifs Infrarouge et Phys. Thermique, Ecole de Phys. et Chimie, Paris, France).
Polymer (GB), vol.24, no.5, p.537-42 (May 1983).
The influence of thermal history on the structure of gelatin gels has been investigated by measuring the specific optical rotation $[\alpha]_\lambda$ at $\lambda=436$ nm. The helix content χ in the gels was derived by reference to the native collagen. Two types of thermal treatments have been applied: (a) cooling and heating at constant rates, and (b) quenching and annealing for long periods. The authors' results support the idea that the gels are nonequilibrium systems and exhibit thermal hysteresis. The kinetics of helix formation were analysed by the Avrami theory and compared to other techniques. The stability of the structures formed suggests the existence of several mechanisms of hydrogen bonding of the helices: disordered aggregation or partial collagen renaturation. (18 refs.)

73377 Studies on conductivity of nickel soaps in benzene-methanol mixtures. K.N.Mehrotra, R.Kachhwaha, S.C.Chopra (Dept. of Chem., Univ. of Jodhpur, Jodhpur, India).
Trans. SAEST (India), vol.17, no.4, p.307-13 (Oct.-Dec. 1982). [received: May 1983]
The conductometric measurements of solutions of nickel laurate in mixtures of benzene and methanol of varying composition have been used to determine the critical micelle concentration. The Debye-Huckel-Onsager-theory of electrolytic conductance is not applicable to the solutions of nickel laurate and the soap behaves as a weak electrolyte in solution. (6 refs.)

73378 The resolution times of water-in-oil emulsions subjected to external electric fields. T.J.Williams, A.G.Bailey (Dept. of Electrical Engng., Univ. of Southampton, Southampton, England).
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.39-44
The application of an external electric field to a water-in-oil emulsion induces coalescence of the suspended water droplets. As the droplets grow their terminal speeds increase. In consequence, the resolution time of the emulsion, into its constituent phases, decreases in the presence of the electric field. The theoretical treatment models the emulsion droplets as monodisperse and cubically packed. The theoretical expression for emulsion resolution time agrees well with experimental data. (5 refs.)

73379 Current voltage characteristic of a cylindrical electrostatic precipitator. J.Cross (Div. of Fossil Fuels, CSIRO, North Ryde, NSW, Australia).
Electrostatics 1983. Sixth Conference on Electrostatic Phenomena, Oxford, England, 13-15 April 1983 (Bristol, England: IOP 1983), p.123-8
A cylindrical experimental electrostatic precipitator, which operates in conjunction with a pilot-scale furnace, was built to investigate the precipitability of fly ashes from different coals. The current-voltage characteristics of the precipitator have been investigated for a number of fly ashes with and without trace additives to aid precipitation. The curves obtained can be related to the behaviour of the ash and the conditions in the precipitator. (2 refs.)

82.80 CHEMICAL ANALYSIS AND RELATED PHYSICAL METHODS OF ANALYSIS

73380 Supersonic jets, rotational cooling, and analytical chemistry. J.M.Hayes, G.J.Small (Dept. of Chem., Iowa State Univ., Ames, IA, USA).
Anal. Chem. (USA), vol.55, no.4, p.565A-74 (April 1983).
Given a complex sample, such as shale oil or a biological specimen, is it too much to ask for a direct quantitative analysis that affords selectivity and sensitivity? The authors think not and hope that the article will allow the reader to share their optimism. To date the most widely used direct analysis technique for such samples has been capillary column/gas chromatography/mass spectroscopy (CC/GC/MS). A major problem is that 'dirty' samples cause rapid degradation of the capillary column. Thus, an extraction or prefractionation step frequently is used to clean up the sample prior to analysis. In addition, for isomeric species, CC/GC/MS must achieve chromatographic resolution to effect an analysis. In principle, electronic absorption or emission spectroscopy is the basis for one such detector. This is because electronic-vibrational (vibronic) transition energies and relative intensities are extremely sensitive to subtle changes in molecular structure. (13 refs.)

73381 Spectrophotometric determination of atmospheric nitrogen monoxide and nitrogen dioxide after collection with [*N,N′*-ethylenebis(salicylideniminato)]cobalt. K.Ishil, K.Aoki (Tokyo Metropolitan Res. Inst. for Environmental Protection, Tokyo, Japan).
Anal. Chem. (USA), vol.55, no.4, p.604-8 (April 1983).
A new method for sampling and determining NO and NO_2 in the atmosphere is investigated. Atmospheric NO and NO_2 are collected in a solution of [*N,N′*-ethylenebis(salicylideniminato)]cobalt (Co(salen)) in *o*-dichlorobenzene. NO reacts with Co(salen) reversibly yielding a nitrosyl complex (Co(salen)NO), which is converted to a nitro complex by air oxidation in the copresence of aminoethanethiol in an 83% yield. NO_2 is absorbed by

Co(salen) solution irreversibly. The product compound can easily be decomposed by stripping with aqueous alkaline solution, yielding the NO_2^- ion quantitatively. The nitro compound and the NO_2^- were quantified spectrophotometrically with a Griess-type reagent. In usual sampling conditions, O_3, NH_3, SO_2, CO, and H_2O did not interfere with the present method. The detection limits were 2 ppb.h (NO) and 1 ppb.h (NO_2). (20 refs.)

73382 Use of secondary ion emission for investigating the distribution profiles of elements and compounds in various film compositions. A.G.Koval, V.N.Mel'nikov, V.V.Bobkov, E.P.Biryukov, N.A.Kapralova (Kharkov State Univ., Kharkov, Ukrainian SSR).
Bull. Acad. Sci. USSR, Phys. Ser. (USA), vol.46, no.7, p.123-8 (1982). Translation of: *Izv. Akad. Nauk SSSR Ser. Fiz.*, vol.46, no.7, p.1346-51 (1982). [received: May 1983] (Proceedings of the XVIII All-Union Conference on Emission Electronics, Moscow, USSR, Dec. 1981).
The method of layer ion analysis is very promising for investigating thin films and transition zones of various solid-state electronic devices. The principal distinctive features of the method are the high degree of depth localization (~10 Å), very high sensitivity (up to 10^{-5}-10^{-7} wt.%), the possibility of determining the composition and distribution of chemical compounds in the system under consideration, and also the possibility of obtaining quantitative data on the distribution of elements and compounds in multicomponent systems. (10 refs.)

73383 Spectroscopic and electrochemical studies on ruthenium(II) complexes containing diazadiimine ligands. N.Kitamura, Y.Kawanishi, S.Tazuke (Res. Lab. of Resources Utilization, Tokyo Inst. of Technol., Yokohama, Japan).
Chem. Phys. Lett. (Netherlands), vol.97, no.1, p.103-6 (6 May 1983).
Newly prepared ruthenium(II) complexes, RuL_3, containing 3,3'-bipyridazine, 6,6'-dimethyl-4,4'-bipyrimidine, and 4-methyl-2-(2'-pyridyl)pyrimidine as ligands (L) were studied by absorption and emission spectroscopy as well as by cyclic voltammetry. The metal-to-ligand charge-transfer absorption spectra and the photocatalytic ability of these RuL_3 complexes were discussed on the basis of the redox properties of L and RuL_3. (12 refs.)

73384 Atmospheric pressure ion evaporation-mass spectrometry. J.V.Iribarne, P.J.Dziedzic (McLennan Phys. Labs., Univ. of Toronto, Toronto, Canada), B.A.Thomson.
Int. J. Mass Spectrom. & Ion Phys. (Netherlands), vol.50, no.3, p.331-47 (15 May 1983).
The analytical possibilities of atmospheric pressure ion evaporation-mass spectrometry (APIE-MS) have been explored. The characteristics of the ion source have been studied. The method has been tested with a range of compounds and has been proven successful with most monovalent ions, both inorganic and organic; transition metals and most inorganic complexes are exceptions. The successful applications include alkaloids, amino acids, sulfonamides, vitamins and in general any compounds which contain a basic nitrogen atom or acidic groups. Certain neutral molecules also evaporate, clustered with ions. Calibration procedures for quantitative application have been developed. The relation of the intensity of mass peaks obtained with this source to molecular weight and structure and to surface activity, and the potential analytical value of the method are discussed. (13 refs.)

73385 In situ neutron activation analysis of and the neutron capture cross-section for $^{90}Sr^+$. L.A.McVey (Pacific Northwest Lab., Richland, WA, USA), R.L.Brodzinski, T.M.Tanner.
J. Radioanal. Chem. (Switzerland), vol.76, no.1, p.131-7 (1983).
Neutron activation analysis has been investigated as an in situ method for determination of ^{90}Sr. The thermal neutron capture cross-section for the $^{90}Sr(n,\gamma)^{91}Sr$ reaction has been measured to be 14.0 ± 2.4 mb which is in disagreement with the currently accepted literature value. The suitability of this reaction and the fast neutron reactions, $^{90}Sr(n,p)^{90}Rb$ and $^{90}Sr(n,\alpha)^{87}Kr$, for the in situ determination of ^{90}Sr is discussed. (5 refs.)

73386 Calculated gamma-ray and/or neutron attenuation coefficients in 14 MeV neutron activation analysis. A.G.Elayi (Dept. of Phys., Univ. of Baghdad, Baghdad, Iraq).
J. Radioanal. Chem. (Switzerland), vol.76, no.1, p.203-13 (1983).
A program of theoretical and experimental work was performed to develop a mathematical model which can represent all the parameters of the neutron activation analysis operation. Absolute techniques are avoided by using a sample containing the same element as the reference but having a different geometry and weight. This model is applied to determine the neutron, gamma-ray and neutron-and-gamma-ray self-shielding of the sample in relation with the number of counts in the total absorption peak. The results obtained should be applied within the limitations of the method. (9 refs.)

73387 Free-sulphur presence in steels. L.S.Caputi, G.Luzzi (Dipartimento di Fisica, Univ. della Calabria, Cosenza, Italy).
Lett. Nuovo Cimento (Italy), vol.37, ser.2, no.1, p.5-8 (7 May 1983).
A new investigation technique, consisting in mechanically scraping sample surface and then performing Auger measurements in the zone, is described. Large S quantities are sometimes found in steels; this S presence seems to be due to free and mobile atoms, presumably coming from grain boundaries. (11 refs.)

73388 Normal and high pressure synthesis of mixed ruthenium-rhodium oxides of the rutile type. M.P.Herrero Fernandez, M.A.Alario Franco, J.C.Joubert (Inst. de Quimica Inorganica 'Elhuyar' CSIC, Madrid, Spain).
Mater. Res. Bull. (USA), vol.18, no.3, p.347-53 (March 1983).
A series of mixed ruthenium-rhodium oxides with general composition $Ru_{1-x}Rh_xO_y$ ($0<x<0.5$) has been prepared at normal and high pressures. The materials obtained at room pressure have a rutile structure and $y=2$. At 60 Kbar, an orthorhombic distortion of the rutile structure is observed for $0.3<x<0.4$. At the maximum distortion the unit cell parameters are $a=4.429(3)$ Å, $b=4.571(3)$ Å and $c=3.0972(9)$ Å. (13 refs.)

73389 ^{252}Cf plasma desorption in ion implanted mica. M.Maurette (Lab. Rene Bernas, Orsay, France), A.Banifatemi, S.Della-Negra.
Nature (GB), vol.303, no.5913, p.159-61 (12 May 1983).
^{252}Cf plasma-desorption mass spectrometry was first used to determine the masses of heavy molecules of biological interest. In this technique ^{252}Cf fission fragments penetrate a thin deposit of material (10^5 cm^{-2}) inducing the desorption of neutral and ionized species. The ionized species are accelerated by an external electrical field and their mass analysed using a time-of-flight (TOF) mass spectrometer run in the coincidence mode with each fission fragment. The authors have tried to assess the analytical and/or simulation potential of heavy-ion stimulated desorption of ions (HISD) in other fields ranging from the so-called 'gas-grain' interactions in astrophysics to the complex ageing of surfaces exposed to strongly ionizing environments in fast neutron fission reactors and fusion reactors. The authors outline the potential of HISD for investigating ion implantation effects in insulators and report a very strong enhancement in the HISD of ionized species from ion implanted mica. This enhancement, which generates heavy-ion clusters up to mass ~500 AMU, grows around a critical fluence of implanted ions, and originates from two distinct types of radiation damage defects. (9 refs.)

73390 Microanalysis for microelectronics. E.Fuchs (Siemens AG, Munchen, Germany).
NTG-Fachber. (Germany), vol.82, p.82 (1983). In German. (Grossintegration (Large Scale Integration), Baden-Baden, Germany, 7-9 March 1983).
For a region of about one micron diameter, the methods described are: an X-ray microprobe, an Auger electron microprobe, a secondary ion mass spectrometer and an electron microscope. The Auger electron technique is used to examine doping profiles. An example given for the implantation of boron in silicon quotes a graph of concentration versus depth. To obtain a pictorial image of a semiconductor component, grinding, polishing and etching have been carried out to enable the sample to be irradiated by 100-200 keV electrons and then examined over a thickness range of 10-100 nm by a transmission electron microscope. (no refs.) *G.C.*

73391 Determination of trace amounts of phosphate in river water by flow-injection analysis. S.Motomizu, T.Wakimoto, K.Toei (Dept. of Chem., Faculty of Sci., Okayama Univ., Okayama-shi, Japan).
Talanta (GB), vol.30, no.5, p.333-8 (May 1983).
A flow-injection analysis system for the determination of trace amounts of phosphate in river water has been developed. The phosphate is reacted with molybdate and Malachite Green in acidic medium to form a green species, the absorbance of which is measured at 650 nm. Phosphorus (as inorganic phosphate) can be determined at the level of several ng/ml in water. Analyses can be done at a rate of up to 40 per hour. (23 refs.)

73392 Spectrophotometric determination of micro amounts of nitrite in water and soil. Qian-feng Wu, Peng-fei Liu (Shaanxi Monitoring Station of Environmental Protection, Xian, China).
Talanta (GB), vol.30, no.5, p.374-6 (May 1983).
A spectrophotometric method for determination of micro amounts of nitrite in water and soil with *p*-aminoacetophenone and resorcinol is described. The interference of foreign ions can be eliminated by masking with complexing agents. Beer's law is obeyed up to 20 μg of NO_2^- in 60 ml of solution and the molar absorptivity at 435 nm is 5.27×10^4 $1.mole^{-1}.cm^{-1}$. The colour is stable for 10 hr. Results obtained by using the proposed method for water and soil samples agree well with those obtained by the Saltzman standard method. (11 refs.)

73393 Comments on accuracy in mass-spectrometric gas analysis. A.Breth, R.Dobrozemsky, B.Kraus (Phys. Dept., Austrian Res. Centre Seibersdorf, Seibersdorf, Austria).
Vacuum (GB), vol.33, no.1-2, p.73-6 (Jan.-Feb. 1983). (Proceedings of the 2nd Joint Meeting of the Roland Eotvos Physical Society (Vacuum Physics and Thin Films Sections) and the Austrian Vacuum Society, Brunn am Gebirge, Austria, 27-29 Oct. 1981).
Analysis of mass spectra from gases or gas mixtures has become a routine procedure in modern vacuum technology. The interpretation of these spectra, however, is straightforward only in very simple cases. In practical work, especially if oxygen-bearing gases dominate the spectrum, the defolding of peaks at interfering mass numbers turns out to be difficult, even if the cracking patterns are known precisely and do not change during the measurement. Changes in the cracking patterns may be caused by reactions at the hot filament, by sorption processes, by ESD, etc. Although the basic aspects of these disturbances are fairly well known, there is little knowledge about their influence on the accuracy of the calculated gas composition. In this contribution the authors give a discussion of experimental results (achieved with a commercial RGA) concerning the influence of disturbing effects on the calculated gas composition, with special emphasis on mixtures of CO and CO_2. 86.00 ENERGY RESEARCH AND ENVIRONMENTAL SCIENCE

86.10 ENERGY RESOURCES AND THEIR UTILISATION

(inc. economic aspects; for nuclear engineering and nuclear power studies, see 28.00)

86.10B Fossil and other fuels

73394 Precious granules—source of energy and reducing agent. D.Bocker, M.Erken, J.Heuter, H.Kreusing (Rheinische Braunkohlenwerke AG, Koln, Germany).
Energie (Germany), vol.35, no.3, p.35-7 (March 1983). In German.
The paper provides an overall description of a plant for coking lignite. The plant was constructed by Lurgi under licence from Salem Corporation, USA. Waste gases and heat are utilised in the plant's energy requirements, resulting in an 'energy efficient' and 'environment friendly' coking process. The larger, second part of the paper deals with the properties and usage of the coke. Besides being a fuel, it is also used in chemical processes, in metallurgy, filters and electrodes. Current production of 110000 t pa is to be more than doubled by a second plant in 1985. (6 refs.) *P.R.S.*

73395 An economic flame—new methods of burning dust in industrial processes. U.Wiedmann (Korting Hannover AG, Hannover, Germany).
Energie (Germany), vol.35, no.3, p.39-41 (March 1983). In German.
The author describes his company's new CirCal dual fuel firing system for 0.5 to 2.0 MW outputs. The burners use a mixture of coal dust with 5-10% of oil or gas or alternatively lignite or wood dust with an optional addition of up to 5% of oil or gas. Changing of fuel is accomplished without interruption as are remotely controlled flame characteristics/temperature changes. Several systems are already installed and have proved to be successful. The return on investments in changing to these burners, can be less than a year at current fuel costs. (7 refs.) *P.R.S.*

73396 Design of a liquid fuels supply model for US policy analysis. J.Barhen, R.G.Alsmiller,Jr., C.R.Weisbin (Oak Ridge Nat. Lab., Oak Ridge, TN, USA), F.Morra, V.A.Kuuskraa, D.M.Nesbitt, R.L.Phillips.
Energy (GB), vol.8, no.3, p.169-97 (March 1983).
The purpose of the paper is to call attention to the existence of this important new analytical tool, to provide a potential analyst with a reasonably complete description of its essential features, and to discuss the benchmarking completed and underway. Detailed network diagrams, process equations, and sources of data are given. Twelve depletable resource processes are represented. These include in situ and surface retorting of western oil shale, tar sands, western and eastern conventional onshore production, three types of enhanced oil recovery, eastern and western offshore recovery, and Alaskan onshore and offshore production. Details of the LFS model equations used to determine the equilibrium prices and quantities of liquid fuels are included. The fundamental data parameters which provide the computational basis for each supply technology are calculated from technology specific relationships between marginal cost and supply. LFS results are compared to projections of the National Energy Policy Plan. It is found that the LFS results generally fall within stated NEPP uncertainty ranges. A comprehensive sensitivity analysis capability, developed in conjunction with the LFS formulation, has been indispensible in identifying the differences in the calculated results. (60 refs.)

73397 Policies to reduce OEDC vulnerability to oil-supply disruptions. D.M.Kline, J.P.Weyant (Terman Engng. Center, Stanford Univ., Stanford, CA, USA).
Energy (GB), vol.8, no.3, p.199-211 (March 1983).
A number of proposals for reducing the level of exposure of the oil importing countries to oil supply interruptions are reviewed and contrasted. Although none of these options is without cost or complication, several appear to offer significant benefits relative to the status quo. Now is the time to fill the current void in energy emergency planning. (13 refs.)

73398 The Alaskan gas pipeline conflict. P.Savich, K.W.Hipel, N.M.Fraser (Dept. of Systems Design Engng., Univ. of Waterloo, Waterloo, Ontario, Canada).
Energy (GB), vol.8, no.3, p.213-24 (March 1983).
A new conflict analysis technique is employed to study the dispute surrounding the selection of a natural gas pipeline route to transport gas from the American state of Alaska and also northern Canada to southern markets in the United States and Canada. The improved metagame analysis algorithm is the type of conflict analysis method that is used for providing a framework to study systematically the Alaskan gas pipeline controversy and to put the historical information into proper perspective. In addition, the methodology is utilized for predicting the possible feasible political solutions to the conflict. (41 refs.)

73399 On gasohol and energy analysis. M.A.Johnson (Res. & Dev. Div., British Gas Corp., London, England).
Energy (GB), vol.8, no.3, p.225-33 (March 1983).
Energy analysis contributed to the public debate on the gasohol programme in the US, where this analysis became a legal requirement. The published energy analyses for gasohol are reviewed and we assess their inherent assumptions and data sources. The analyses are normalised to SI units to facilitate comparisons. The process of rationalising the various treatments uncovered areas of uncertainties, particularly in the methodologies which could be used to analyse some parts of the process. Although the definitive study has still to be written, the consensus is that maize to fuel ethanol via the traditional fermentation route is a net consumer of energy. (13 refs.)

73400 Hydrogen as a fuel. J.S.Wallace, C.A.Ward (Dept. of Mech. Engng., Univ. of Toronto, Toronto, Ontario, Canada).
Int. J. Hydrogen Energy (GB), vol.8, no.4, p.255-68 (1983).
Hydrogen, used as fuel, has a number of attractive features that make it a leading candidate in the search for an alternative to the dwindling and progressively less reliable supply of fluid hydrocarbon fuels. Hydrogen produced by electrolysis using hydro-or nuclear-generated electricity will be available in Canada at prices competitive with other portable forms of energy before the end of the century. The paper examines the use of carbon-free electrolytic hydrogen as a motor vehicle fuel and as a fuel for fuel cells. A review of onboard hydrogen storage systems indicates that the propulsion power unit of hydrogen-fueled vehicles must be considerably more efficient than present gasoline-fueled internal combustion engines in order to compensate for the larger size and greater weight of hydrogen storage systems. Hydrogen-fueled internal combustion engines are more efficient than similar gasoline-fueled engines, but the improvement is not sufficient to offset the storage system limitation. Fuel cells operate with much higher efficiency than internal combustion engines, especially at partial loads. A comparison between H_3PO_4 and KOH fuel cells show that where carbon-free hydrogen is available from the onboard storage system, the KOH fuel cell offers the higher level of performance. 86.10D Wind energy

73401 An analysis of wind power potential in Greece. D.P.Lalas, H.Tselepidaki, G.Theoharatos (Dept. of Meteorology, Univ. of Athens, Athens, Greece).
Sol. Energy (USA), vol.30, no.6, p.497-505 (1983).
An analysis of the available wind data for the Aegean Sea region of Greece is carried out to ascertain its potential for wind energy development. The effect of the limited number of daily observations available on the accuracy of the mean wind speed and annual wind energy estimates is ascertained. The applicability of the Weibull distribution is then examined and plots of the Weibull parameters are given. The annual average wind energy flux is calculated and found to be quite high (in excess of 600 W/m^2 per yr at 10 m) which makes the Aegean Islands likely candidates for wind power utilization. (24 refs.)

86.10F Tidal and flow energy

(inc. water-wave energy)

73402 Hydropowerplants as a rationalisation element in the Czechoslovak power and fuel balance. L.Tekel.
Bull. EGU (Czechoslovakia), no.90, p.20-9 (1982). In Czech.
Discusses the possibilities for a hydropower contribution to the fuel and power balance of Czechoslovakia. (16 refs.)

73403 Change in the ice and thermal regime of the Vilyui river in the lower pool of the Vilyui I-II hydrostation. S.N.Nazarenko, N.B.Sakharova.
Hydrotech. Constr. (USA), vol.16, no.8, p.431-5 (Aug. 1982). Translation of: *Gidrotekh. Stroit. (USSR)*, vol.16, no.8, p.23-6 (Aug. 1982). [received: March 1983]
Shows that the effect of the hydrostation on various characteristics of the winter regime of the river extends over a considerable distance. The increase of the winter levels is traced on a stretch more than 1000 km long, i.e. practically to the mouth. A noticeable decrease of the water temperature in the summer months is observed on a stretch up to 800 km long, and an increase of temperature in the spring and fall months in a stretch 600 km long. Disturbances of the ice regime of the river (a shift of the times of freezeup and breakup) do not extend farther than 400 km, in which case migration of the ice edge occurs in the 35-60-km stretch closest to the hydrostation and the formation of secondary polynyas in the ice cover is noted on rapid stretches at a distance up to 200 km. Consideration of the changes in the natural ice and thermal regime of the river under the effect of activity of a hydrostation is necessary. (1 ref.)

73404 Optimization of the filling and drawdown regimes of a regulating reservoir of the Kuban' cascade. A.F.Fedosyuk, I.L.Krasnik, A.B.Kaganovich.
Hydrotech. Constr. (USA), vol.16, no.8, p.470-4 (Aug. 1982). Translation of: *Gidrotekh. Stroit. (USSR)*, vol.16, no.8, p.50-3 (Aug. 1982). [received: March 1983]
Optimizing the filling of the Great regulating reservoir makes it possible to increase the efficiency of using the flood, which provides additional production of electric energy. Optimization of the discharges along the Great Stavropol' Canal on the basis of the criterion of minimum specific discharges of hydrostations of the cascade and approximation of the regime of the hydrostations to these conditions additionally increase the effectiveness of using the stream. (2 refs.)

73405 Influence of conception development for energy use of mid and low course of Neretva on the design of hydro plant 'Mostar'. M.Pavlovic, S.Radovic.
Elektroprivreda (Yugoslavia), vol.36, no.1-2, p.17-27 (Jan.-Feb. 1983). In Croatian.
Presents the conception development for energy use of water belonging to mid and low course of Neretva for the period from 1953, when the first basic design was developed, until present days when the solutions have been adapted to meet the requirements for variable energy from one side, and the requirements of other potential users of water and space, from the other side. (13 refs.)

73406 An experimental study on the wave-power energy conversion. S.Miyae, Y.Teguri (Kanazawa Univ., Kanazawa, Japan).
Mem. Fac. Technol. Kanazawa Univ. (Japan), vol.15, no.2, p.87-94 (Nov. 1982). In Japanese.
Reports an experimental study on the wave-power energy conversion system depending on the wave-overtopping. This system consists of a converging wave channel, an overrunning slope and an elevated storage basin. The density of wave-power is amplified by the converging channel. Then the wave was elevated to the storage basin by the overrunning slope. The water in the storage basin discharged back to sea level via a low-head turbine driving a generator. The authors carried out an experiment on this system by using a regular wave, and as a result the optimum shape of the overrunning slope and the converging bank was obtained. (8 refs.)

86.10H Geothermal energy

73407 Forty years of electric-power development in Kenya. M.Kansara, N.S.Walkade (Dept. of Electrical Engng., Univ. of Nairobi, Nairobi, Kenya).
Energy (GB), vol.8, no.4, p.317-21 (April 1983).
The power system in Kenya has grown from a series of small isolated stations serving limited areas to one comprising a large power grid. The total installed capacity has increased from 10,314 kWe in 1938 to 102214 kWe at the time of independence in 1963. It has 460100 in 1978, while projected supply and demand for electricity in the year 2000 are anticipated to be 1,100,000 and 1,267,000 kWe respectively, thus showing a deficit of 167000 kWe,. (4 refs.)

73408 Faisabilite technique et economique de la geothermie basse energie en Europe (Technical and economic feasibility of deep geothermal energy in Europe. Annexes).
Report EUR 8241/II FR, Comm. European Communities, Luxembourg (1982), 343 pp. In French. Contract 640-78 EGF.
The report is a very comprehensive one, published by the Commission of the European Communities. It is split into some fourteen main sections. These include the determination of the hydrogeological and geothermal characteristics, the definitions of the provisional technical programmes and those of boring and piping. It reviews climatic conditions in relation to the covering of requirements by geothermal sources and deals with heat exchangers, heat pumps, costs and the transport of geothermal type water. Examples are given of the uses of heat in industry and adoption to the use of geothermally based energy. Examples are malt plants, breweries, milk installations, tanneries and mining industries. Details are given of existing geothermal installations, conditions in Italy and France and some recommendations are finally given.

86.10K Solar energy

73409 Utilization of solar energy in people's economy. S.Keresztes.
Energ. & Atomtech. (Hungary), vol.36, no.2, p.68-71 (Feb. 1983). In Hungarian.
In the plans for research and development of foreign countries, the activity connected with solar energy gets a role of larger and larger stress. Although this work has been carried out in some countries for more than 20 years, it has only been pointed out really by the increase in the problems of oil crisis and environmental pollution. In very many countries a stately organized and financed solar energy research is carried out. In spite of the widespread opinions, solar energy utilization in Hungary can be carried out economically by means of correspondingly differentiated approach. The exploitation of these possibilities is in the interest of people's economy. The Hungarian industry is able to produce equipments corresponding to the current situation of solar techniques, a large part of which can be produced expediently of aluminium. (2 refs.)

73410 High temperature solar electrothermal processing—zinc from zinc oxide. E.A.Fletcher, J.E.Noring (Dept. of Mech. Engng., Univ. of Minnesota, Minneapolis, MN, USA).
Energy (GB), vol.8, no.4, p.247-54 (April 1983).
The authors examine the feasibility of using sunlight to reduce the amount of electric power and/or fossil fuel needed to win metals from their ores and other compounds. The uniqueness of highly concentrated sunlight as a source of high-temperature process heat makes it attractive. They also examine, in some detail, ZnO as a candidate substance for exploratory experimental studies. They have mapped out, in temperature-pressure coordinates, the properties of the working substance and the thermodynamic performance of an archetype device as a guide to the temperature-pressure regime in which experimental studies might most profitably be undertaken. (14 refs.)

73411 The solar radiation resource. A.Rabl, F.von Hippel (Center for Energy & Environmental Studies, Princeton Univ., Princeton, NJ, USA).
Energy (GB), vol.8, no.4, p.295-316 (April 1983).
The authors discuss the characteristics of solar radiation which are most useful for the assessment of solar technologies. Graphs are presented which show the total annual insolation incident on the principal tracking and non-tracking collectors. Additional graphs are developed for the latitudinal and seasonal variations of solar radiation in the absence of an atmosphere. These are then compared with measurements averaged over the US SOLMET sites to provide an understanding of the role of atmospheric effects on the seasonal variations of solar radiation. (15 refs.)

73412 Problems and prospects of solar power stations. K.Kotarska, Z.Kotarski.
Przegl. Elektrotech. (Poland), vol.58, no.11-12, p.345-50 (Nov.-Dec. 1982). In Polish.
World-wide development in the field of conversion of solar energy into electrical energy is presented. Solar power stations both with centralized and decentralized conversion are described. The present state and prospects of solar cell power stations on the Earth and in outer space with direct conversion of solar into electrical energy, are reviewed. (13 refs.)

73413 Preliminary research in the measurement of the solar radiation by transient technique. S.X.Cheng, X.S.Ge (Dept. of Modern Mech., Univ. of Sci. & Technol. of China, Hefei, China).
Sol. Energy (USA), vol.30, no.5, p.391-5 (1983).
A new technique for measuring the solar radiation is presented. It consists of measuring the heating and cooling rate of the sensor of the instruments when the sensor is exposed to or shielded from the incident solar radiation. The experimental apparatus are described in the paper along with the theoretical analyses of the technique. Solar radiation data using the apparatus are compared with those obtained through other means. The agreement is good. (8 refs.)

73414 Climatic predispositions of Yugoslavia for solar energy application. U.V.Desnica, N.B.Urli, B.Pivac (Rudjer Boskovic Inst., Zagreb, Yugoslavia).
Sol. Energy (USA), vol.30, no.5, p.401-12 (1983).
The paper is a summary report of an extended investigation of the practical usability of solar energy in Yugoslavia. The main tool for calculation was TRNSYS simulation program. Meteorological data and technical parameters of typical commercial solar devices were used as input data. Solar flux data on tilted planes were obtained by means of the Liu and Jordan method. For five locations, chosen to characterize all typical climatic regions in Yugoslavia, a detailed hour by hour simulation of the performance of the typical commercial domestic hot water solar heating system (DHW) was carried out. In summer the efficiency of such a device was similar for all locations, ranging from 40 to 45 per cent. In the winter months the efficiency varied from 30 per cent in sunny coastal regions to less than 10 per cent in polluted urban areas. The same type of calculations were worked out for a combined solar-traditional space-heating system, including the investigation of the influence of some important parameters on the efficiency of the solar part of the system. Calculations show that in very polluted urban areas only low-temperature load heat exchangers are to be recommended; in the coastal and southern parts of the country, however, high working temperature (50°C) is allowed which results in the average efficiency of the system of more than 25 per cent even if the worst month and even if the ordinary black-paint, double glazed collectors are used. (7 refs.)

73415 Digital data gathering for solar energy measurement. P.J.Hession, W.J.Bonwick (Dept. of Electrical Engng., Monash Univ., Clayton, Victoria, Australia).
Sol. Energy (USA), vol.30, no.5, p.441-6 (1983).
A new and inexpensive instrument is described which monitors, integrates and records the millivolt output of solar radiation meters and the design principles are given. Readouts are provided which indicate the instantaneous solar power, the running energy total and also the energy available over completed 1 hr, 1 day and 1 week intervals. The instrument has been in operation for over 12 months in Victoria, Australia and a set of weekly readings for this period is given. The accuracy of the recorded data is limited predominantly by the solar radiation meter itself. (5 refs.)

73416 Diffuse and global solar spectral irradiance under cloudless skies. D.T.Brine, M.Iqbal (Dept. of Mech. Engng., Univ. of British Columbia, Vancouver, Canada).
Sol. Energy (USA), vol.30, no.5, p.447-53 (1983).
A simple empirical model to calculate solar spectral diffuse and global irradiance under cloudless skies is presented. This formulation takes into account absorption of radiation by molecules such as O_3, H_2O and the uniformly-mixed gases. Attenuation by Rayleigh scattering and aerosol extinction are included. Aerosol attenuation is calculated through Angstrom's turbidity parameters α and β. The diffuse radiation is assumed to be composed of three parts: (1) Rayleigh-scattered diffuse irradiance; (2) aerosol-scattered diffuse irradiance; and (3) irradiance arising out of multiple reflections between the atmosphere and the ground. The global irradiance is the sum of these three components of diffuse irradiance plus the direct irradiance. The input parameters include an extraterrestrial spectrum, zenith angle, turbidity coefficient β, wavelength exponent α, ground albedo ρ_g, water vapor content and ozone content. The model is shown to yield very good results up to air mass two when compared to accurate theoretical calculations. No comparisons with measured spectra are presented because of a lack of accurate specifications of input parameters. Results are presented to show the effect of variation of certain of the input parameters. (26 refs.)

73417 Ideal second stages in tandem with spherical mirrors. E.M.Kritchman (Enrico Fermi Inst., Univ. of Chicago, Chicago, IL, USA).
Sol. Energy (USA), vol.30, no.5, p.481-2 (1983).
When focused by a spherical mirror, the image of the sun is substantially wider than when focused by a paraboloid mirror. Yet, the importance of spherical mirrors as means to concentrate solar energy, may be emphasized by their potential low cost, e.g. when fabricated from inflated aluminized mylar. In addition their low concentration capability may be improved by the introduction of second stage elements at their focal plane. Formulae that describe the concentration C_1 of the (primary) spherical concentrator are derived here and compared to the concentration capability C of the combined two stage concentrator, along with some computed data. (8 refs.)

73418 An experimental parabolic cylindrical concentrator: its construction and thermal performance. R.V.Heiti, G.Thodos (Northwestern Univ., Evanston, IL, USA).
Sol. Energy (USA), vol.30, no.5, p.483-5 (1983).
The construction, operation and thermal performance of a parabolic cylindrical solar energy concentrator is considered. The materials used in construction and their reasons for being used are pointed out and the operational procedure, modes of operation and efficiency obtained is discussed. (no refs.)

73419 Comments on paper [simple multiple wick solar still: analysis and performance]. P.Gandhidasan (Univ. of the West Indies, Faculty of Engng., St. Augustine, Trinidad).
Sol. Energy (USA), vol.30, no.5, p.492 (1983).
Presents the comments of P. Gandhidasan on the paper 'simple multiple wick solar still: analysis and performance' by Sodha et al. and also the reply from M.S. Sodha. The part of the paper under discussion is the equation dealing with convective heat transfer from water to glass. (no refs.)

73420 Solar flux distributions from circular cyclindrical concentrators. J.K.Sharma, A.Dang, H.P.Garg, S.S.Mathur (Center of Energy Studies, Indian Inst. of Technol., New Delhi, India).
Sol. Energy (USA), vol.30, no.6, p.507-12 (1983).
Solar flux distributions produced by circular cylindrical concentrators have been determined. An integral relationship for evaluating the energy density distribution on receivers of arbitrary shape has been developed. The solar intensity distributions have been calculated for flat and cylindrical receivers. The developed formulae are applied to uniform and non-uniform source intensity distributions. The effect of longitudinal defocusing on the intensity distributions on receivers has also been considered. In case of cylindrical receivers, the local concentration decreases with an increase in the radius of receiver as well as with rim angle β of the receiver. (13 refs.)

73421 The design and performance of ideal solar concentrators based on the prism-assisted cyclindrical reflector. I.R.Edmonds, I.R.Cowling, L.A.Meara, B.Wheeler (Dept. of Phys., Queensland Inst. of Technol., Brisbane, Australia).
Sol. Energy (USA), vol.30, no.6, p.537-43 (1983).
The optical design of an ideal concentrator based on the combination of a cylindrical reflector and refracting prism is discussed and shown to have a number of advantages over other reflector type concentrators. A 20× photovoltaic concentrator is shown to have an optical efficiency of over 70 per cent within the ideal acceptance angle in good agreement with experimental results. (9 refs.)

73422 Terrestrial solar spectral data sets. R.E.Bird, R.L.Hulstrom (Solar Energy Res. Inst., Golden, CO, USA), L.J.Lewis.
Sol. Energy (USA), vol.30, no.6, p.563-73 (1983).
Two data sets are presented that were generated with a rigorous radiative transfer code. One data set is an AM1.5 direct normal spectrum, and the other data set is an AM1.5 global spectrum on a surface tilted 37° from the horizontal towards the Sun. These data are updates to data that are nearing acceptance as standard of the American Society of Testing and Materials. An improved extraterrestrial spectrum and other refinements were made to improve the accuracy of these data sets. A preliminary comparison between modeled and measured data is shown, which supports the accuracy of the data sets. (24 refs.)

73423 Optical properties of compound elastical concentrators. P.G.McCormick (Dept. of Mech. Engng., Univ. of Western Australia, Nedlands, WA, Australia).
Sol. Energy (USA), vol.30, no.6, p.597-9 (1983).
Non-imaging concentrators have received considerable attention in recent years as a result of their ability to accept radiation over a range of incident angles. Ideal cylindrical concentrators, such as the compound parabolic concentrator (CPC), exhibit the highest possible concentration ratio for a given acceptance angle. It has been shown that simple elastic bending can be used to form the reflector profile for a non-imaging concentrator. For low concentration ratios, i.e. 1.5-3.0, the optical properties of optimised concentrators

with flat or cavity absorbers approach that of truncated CPC concentrators. (13 refs.)

73424 Stationary nonimaging concentrator as a second stage element in tracking systems. E.M.Kritchman, K.A.Snail, J.O'Gallagher, R.Winston (Enrico Fermi Inst., Univ. of Chicago, Chicago, IL, USA).
Sol. Energy (USA), vol.30, no.6, p.601-2 (1983).
The University of Chicago solar energy group and GTE Research Laboratories in Waltham, Massachusetts, have recently developed an integrated stationary evacuated concentrating (ISEC) collector tube (see ibid., vol.29, p.575, 1982). It consists of an extended cusp type compound parabolic concentrator (CPC) matched to a tubular selective absorber with the CPC and the absorber integrated into a vacuum enclosure. The outer wall of the enclosure is made by shaping a circular glass tube; the lower cross section of the glass conforms to a CPC profile and is coated with a reflective film, while the upper cross section of the glass is of a circular profile and acts like a transparent entrance window. The vacuum environment inside the enclosure enables the use of a highly reflective front surface silver mirror, increases the lifetime of the selective absorber coating, and minimizes heat loss from conduction and convection. The authors examine the increase in concentration of line focus concentrators that can be achieved by using the evacuated CPC collector tube as a second stage element. (16 refs.)

73425 Etude de faisabilite d'une centrale photovoltaique de taille moyenne (0,5 - 1 MW), avec stockage (Feasibility study for a medium-sized (0.5 - 1.0 MW) photovoltaic power station, with storage).
Report EUR 8196 FR, Comm. European Communities, Luxembourg (1982), 276 pp. In French. Contract 474-78-4 ESF.
The report covers a study between April 1978 and March 1979 at Bois d'Avey, France. The introduction covers the structure of the system, the carrying out of the work and also work subdivision. The first phase is then described, covering generators, identification and also the evaluation of subsystems. The second phase covers the choice of the best solutions for the larger options of the study. These include astronomical, meteorological, economic and energy storage aspects. The third phase of the report deals with general engineering matters concerning the power station. Some details on dimensioning are given, followed by optimisation generally of storage, series-parallel working, DC/AC conversion and general architecture.

73426 Utility interface issues for grid-connected photovoltaic systems. D.Chu, T.Key (Sandia Nat. Lab., Albuquerque, NM, USA), J.Fitzer.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.391-5
Photovoltaic (PV) balance-of-system research and development has focused on interconnection with the utility grid as the most promising future application for photovoltaic energy production. These systems must be compatible with the existing utility grid to be accepted. Compatibility encompasses many technical, economic and institutional issues from lineman safety to revenue metering and power quality. The authors review DOE/PV sponsored research for two of the technical interconnection issues: harmonic injection, and power factor control. Explanations and rationale behind these two issues are reviewed, and the status of current research and plans for required future work presented. (12 refs.)

73427 AC power quality improvement for line-commutated inverters in photovoltaic applications. A.W.Pautzke (Windworks Inc., Mukwonago, WI, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.396-9
Line-Commutated Inverter (LCI) technology provides reliable, efficient and cost-effective DC to AC power conversion for photovoltaic systems. It's only potential shortcoming for large scale use was power quality. In 1980 MIT Lincoln Laboratories and Windworks Inc. recognized the need for power quality improvement in these single phase utility interactive systems. The contract for Further Development of the Single Phase LCI focused on this objective by setting a power quality goal of unity power factor and 5% THD-AC current. An AC network was developed which obtained this goal. Ultimately, the cost impact on the product will be known when minimum guidelines are established for desired power quality. The guidelines must be substantiated by quantified harmonic affects on utility power quality. Unfortunately, these are not established at this time. In lieu of this, current design guidelines are presented. (no refs.)

73428 Energy recovery from gases in blast furnaces.
Tech. Mod. (France), vol.74, no.9-10, p.31-4 (Sept.-Oct. 1982). In French. [received: March 1983]
A method developed in the USSR extracts gas from the mouth of a blast furnace for expansion in a GOUBT compressorless gas turbine, where its pressure falls to a level appropriate for piping to customers. The turbine can function with gas having a wide range of dust. The turbine rotor is coupled directly to an electric generator. Two installations in Japan are depicted. More than 10 years' experiments at the Cherepovets metallurgical plant are described and their results are summarised. (no refs.) *M.B.D.*

86.30 ENERGY CONVERSION

73429 Batteries and energy systems. 2nd edition. C.L.Mantell.
New York, USA: McGraw-Hill (1983), xv+319 pp. [0 07 040031 8]
The following topics were dealt with: thoroughly revised and brought completely up to date, this comprehensive guide covers the full range of today's methods for providing packaged power for civilian, industrial, military, and space applications. Embracing everything from current-producing batteries to regenerative electrochemical systems to photovoltaic solar cells, this unique work spells out the technical where, why, and how of just about any battery or energy system one is likely to encounter. Numerous tables, drawings, and photographs give important facts and data in concise form. For this expanded Second Edition, entirely new chapters have been added on the use of batteries in windmills and on the effect of EMD (electrolytic manganese dioxide) on battery performance. The first book to treat the topic as a coordinated whole, this is a completely updated treasury of solid, practical information on the full spectrum of batteries and energy systems. It will prove invaluable to everyone whose daily work requires a thorough understanding of the properties, components, and operation of batteries—or who has to choose or specify batteries and energy systems that will do the job that needs to be done both efficiently and economically.

86.30E Primary cells

73430 Lithium cells. K.Smrcek, O.Marholova.
Elektrotech. Obz. (Czechoslovakia), vol.72, no.3, p.134-9 (March 1983). In Czech.
Discusses the contemporary problems of lithium cells. The authors turn attention to the main types of primary cells, presents their properties and characteristics and differences with respect to classical types. Further, they mention the complicated problems concerning the secondary cells including the up to now unsolved questions limiting the fast development of a new accumulator with a lithium anode. (13 refs.)

86.30F Secondary cells

73431 In situ Raman spectroscopic studies of the rechargeable low temperature molten salt cell Na/beta″-alumina/S(IV) in $AlCl_3$-NaCl. K.Tanemoto, A.Katagiri, G.Mamantov (Dept. of Chem., Univ. of Tennessee, Knoxville, TN, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.890-2 (April 1983).
The rechargeable cell $Na/\beta''=Al_2O_3/S(IV)$ in $AlCl_3$-NaCl is operated at 180°-250°C and has an open-circuit voltage of 4.2 V. The Raman spectroscopic studies described by the authors were undertaken to provide a better understanding of the chemistry that takes place during discharge and charge processes in the positive electrode compartment. (16 refs.)

86.30G Fuel cells

73432 Energy storage in a fuel cell with bipolar membranes burning acid and hydroxide. A.T.Emren, V.J.M.Holmstrom (Dept. of Phys. Chem., Univ. of Goteborg, Goteborg, Sweden).
Energy (GB), vol.8, no.4, p.277-82 (April 1983).
A battery is described, in which bipolar membranes are used to split water into acid and hydroxide. The liquids may be stored for an indefinite time, and energy may be recovered at room temperature. It is shown that the liquids are able to store about 400 kJ/litre, which roughly corresponds to pumping water up to an altitude of 40 km. Bipolar membranes of low area resistance have been made and tested. The area resistance appears to have been 2-3 Ω cm^2. A battery containing 7 unit cells has been constructed and tested. The maximum output voltage has been 1.8 V. The cost for energy storage is estimated to range from $0.1 to 2.5 per kWh depending on the mode of operation. (5 refs.)

73433 Evaluation of tetrafluoroethane-1,2-disulfonic acid as a fuel cell electrolyte. P.N.Ross,Jr. (Materials & Molecular Res. Div., Lawrence Berkeley Lab., Berkeley, CA, USA).
J. Electrochem. Soc. (USA), vol.130, no.4, p.882-5 (April 1983).
Reports some physical properties of TFEDSA relevant to fuel cell use and preliminary examinations of this electrolyte in fuel cells with hydrogen containing carbon monoxide. The conclusion of this study of TFEDSA as a fuel cell electrolyte is that because of poor conductivity at higher concentration it offers no advantage over H_3PO_4 in fuel cell applications where systems considerations favor cell temperatures above ca. 120°C. (17 refs.)

Hydrogen as a fuel .... See Entry 73400

86.30J Photoelectric conversion: solar cells and arrays

73434 The influence of the interface state on the properties of solar cell semiconductor electrodes. Lin Zhang-da, Zhou Pei-zhen, Chen Yun-qi, Deng Hui-guo, Qi Shang-xue, Wang Chang-heng, Xie Kan (Inst. of Phys., Acad. Sinica, Shanghai, China).
Chin. Phys. (USA), vol.3, no.1, p.36-44 (Jan.-March 1983). [received: May 1983]
An n-Fe_2O_3 film was grown on an n-Si substrate which had undergone surface treatment to form a double layer semiconductor electrode. The influence of the interface state on the electrode properties was studied. From photoluminescence measurements, the authors found that an interface state with high density of states exists lying above the top of the Fe_2O_3 valence band at 1.61 eV. The Fermi level is pinned by this interface state. Using energy band profiles, they give an explanation for the photoluminescence, as well as a theoretical calculation and analysis for the capacity-voltage curves and photo-current-voltage curves. These theoretically calculated curves agree well with the experimental data. This double layer semiconductor electrode with an interface state with high density of states is promising material for

solar cells of good stability and high photo-electric conversion efficiency. (7 refs.)

73435 **Some problems of MIS photovoltaic cells with a dominating minority charge carrier flow.** S.Baratka.
Elektrotech. Obz. (Czechoslovakia), vol.72, no.3, p.153-6 (March 1983). In Czech.
Surveys some problems connected with the performance of MIS photovoltaic cells. It mentions the properties of the oxide layer which influences the no-load voltage. Problems of antireflection surfaces are treated including the light reflection properties of the cells surface. The degradation factors are also described which exist in case of the MIS cells having the upper collector electrode in form of a grid applied directly to the insulation layer. (16 refs.)

73436 **Solar cells. I.** D.Teodorescu.
Elektr. Masch. (Germany), vol.62, no.3, p.72-7 (March 1983). In German.
Describes history and state of the art of solar cells. With monocrystal silicon cells an efficiency of about 20% can be achieved. Polycrystalline and amorphous silicon can be used but with high (over 1000) concentration factors, GaAs cells are more efficient. The average efficiency of mass produced amorphous Si cells is 6% (theoretical: 15%). (no refs.) *J.S.*

73437 **Screen printed CdS/CdTe solar cell.** H.Matsumoto, H.Uda, A.Nakano, Y.Komatsu, K.Kuribayashi, S.Ikegami (Wireless Res. Lab., Matsushita Electric Industrial Co. Ltd., Osaka, Japan).
Natl. Tech. Rep. (Japan), vol.29, no.1, p.120-6 (Feb. 1983). In Japanese.
The preparation conditions of a screen printed CdS/CdTe solar cell, which is prepared on a glass substrate by successively repeating screen printing and heating of each paste (consisting of CdS, CdTe, C and other electrode materials), were investigated. The optimum sintering conditions of CdS, CdTe, C and other electrode materials, were investigated. The optimum sintering conditions of CdS and CdTe films were 690°C for 90 minutes and 620°C for 60 minutes, respectively. Three kinds of solar cells were prepared on 10×10 cm^2 glass substrates by changing the print pattern of the cells. The first had 1 cell on a substrate, the second had 2 small cells connected in series on a substrate, and the last had 10 small cells connected in series on a substrate. The output voltages of these three cells at the optimum loads were 0.45 V, 0.90 V, and 4.5 V, respectively. A lot of the second type cells were produced, and the maximum intrinsic efficiency of 9.0% (5.8% for total substrate area) was obtained. A 24-watt module which consisted of 48-second type cells connecting in series was produced. The module showed photovoltaic characteristics of $V_{OC}=68.5$V, $I_{SC}=0.725$ A, maximum power $=24.1$ W and module efficiency ≈ 5.0% for total substrate area under a 100 mW/cm^2 solar simulator. (14 refs.)

73438 **Use of polymeric materials in the assembly of solar cells.** A.Addeo, V.Bonadies, C.Carfagna, G.Guerra, A.Moschetti (Istituto 'G. Donegani', Naples, Italy), L.Nicolais.
Sol. Energy (USA), vol.30, no.5, p.421-4 (1983).
A new photovoltaic module made of solar cells encapsulated in polymeric matrices is described. The encapsulation system utilizes polymers of the acrylate family which have different thermal and mechanical encapsulate photovoltaic modules. (12 refs.)

73439 **Nouvelles methodes de preparation de materiau semi-conducteur cellules solaires Cu_2S-CdS (New methods for the production of the solar cell semi-conductor material Cu_2S-CdS).** J.Vedel, J.Lahaye, S.Martinuzzi, J.Bougnot.
Report EUR 8210 FR, Comm. European Communities, Luxembourg (1982), 93 pp. In French. Contract 430-78-1 ESF.
Gives a detailed study of the research programme starting with the preparation and characteristics of Cu_2S layers using chemical evaporation. A physiochemical study is then made on the characteristics of aerosols on the conductivity of CdS films. Further sections cover the physical characteristics of thin CdS layers using electrical measurements as a function of temperature to determine reactions, mobility and energy levels. A description of the actual use of responses follows, as applied to areas more than 4 cm^2. A similar section gives details of making and using Cd_2S by 'dipping' as a function of sparking obtained by chemical evaporation. The final section covers the installation of a pilot works and the manufacture of this type of solar cell.

73440 **Omnidirectional proton irradiation of thin and thick solar cells.** M.W.Walkden, A.A.Dollery (Space & New Concepts Dept., Royal Aircraft Establ., Farnborough, England).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.295-300
Proton damage ratios, relating the damage caused by 1 MeV electrons to that caused by protons of various energies, have been found for hemispherical isotropic proton conditions. The proton fluences were incident on either the front or rear of the cell. Six types of cell were used in the study, ranging in thickness from 50 to 250 μm. The proton damage ratios have been found to be much higher than those derived in earlier studies where normal incidence protons were employed, although the differences are somewhat offset by the cell cover glass or rear shield. A comparison is made with the earlier work in conjunction with proton maps AP6 and AP7 with the later AP8 series. (3 refs.)

73441 **Prediction of solar cell performance in space.** R.L.Statler, D.H.Walker (Naval Res. Lab., Washington, DC, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.301-6
Discusses two factors which are important in such predictions. The first is the gradual deterioration of the optical transmissivity of the coverglass and its adhesive layer, using data derived from the solar cell experiment on the Naval Research Laboratory NTS-2 satellite. The magnitude of this effect is shown through the interpretation of satellite data. The second factor is temperature enhanced radiation damage which was observed during radiation experiments at low dose rates on silicon solar cells. These experiments are being carried out at the NRL Cobalt 60 facility. The observed radiation damage is shown to be strongly dependent on the temperature of the silicon cells during irradiation. The magnitude of this effect is shown in its influence on the interpretation of satellite data. (4 refs.)

73442 **Effect of electron flux on radiation damage in GaAs solar cells.** R.Y.Loo, G.S.Kamath, R.C.Knechtli (Hughes Res. Labs., Malibu, CA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.307-9
Compares the defect levels and the power ratio of the GaAs solar cells under various irradiation conditions. IN a 200°C continuous annealing experiment, the GaAs solar cells which were irradiated at a flux of 2×10^9 ecm^{-2} s^{-1} suffered less power degradation than the cells which were irradiated at the same temperature at a higher flux of 4×10^{10} ecm^{-2} s^{-1}. After the continuous annealing experiment, the authors performed a single-step post annealing at 200°C for 40 hr on these irradiated cells. They observed an additional improvement in power recovery only on those cells irradiated at the high flux of 4×10^{10} ecm^{-2} s^{-1}. The DLTS data indicates that the defect density decreases with lower electron flux. Both of these observations strongly suggest that the continuous annealing in GaAs cells can be effective at temperatures as low as 150°C, or even less in a space environment such as geosynchronous orbit. (2 refs.)

73443 **Irradiated solar cells fabricated from gallium-doped/boron-doped FZ and CZ silicon.** J.A.Minahan, N.Neal, D.Dionne, W.E.Taylor (Spectrolab Inc., Sylmar, CA, USA), T.M.Trumble.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.310-15
Compares the tolerance to various fluence levels of 1 MeV electrons of solar cells fabricated from: gallium-doped multipass FZ silicon, boron-doped multipass FZ silicon, gallium doped CZ silicon and boron doped CZ silicon. The FZ materials used for the study were of ultra high purity with low levels of oxygen and carbon. Bulk analysis of gallium doped cold crucible (C^3Z) silicon is included and compared with gallium doped FZ silicon. Bulk analysis of selected wafers in the various crystals was performed by low temperature FTIR and surface photovoltage. Measurement of AMO electrical characteristics and spectral response of solar cells fabricated from these silicon materials before and after 1 MeV electron irradiation are used to compare radiation tolerance of the materials. (11 refs.)

73444 **High efficiency approaches [solar cells].** S.C.Jain (Solid State Phys. Lab., Delhi, India), R.Mertens, R.Van Overstraeten.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.333-9
Thin silicon structures in which carrier and photon reflections occur in both sides offer the possibility of very high efficiencies. High doping levels in these structures must be avoided to obtain emitter and base regions that are transparent for the minority carriers. Highly efficient back-surface fields are low front-surface recombination velocity are additional requirements to achieve high efficiencies. MIS and SIS emitters, though promising from theoretical viewpoint, suffer from technological difficulties and stability problems leaving a moderately doped n-p junction with passivated surface as the optimum emitter structure. Theoretical calculations show that the built-in voltage is the upper limit of V_{oc} in such a cell as the cell thickness becomes small. Bandgap narrowing makes the built-in voltage considerably smaller than the bandgap E_g. (29 refs.)

73445 **A survey of grid technology [solar cells].** P.A.Iles (Applied Solar Energy Corp., City of Industry, CA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.340-7
Discusses grid patterns used to increase the efficiency of almost all forms of solar cells. The author surveys grid design principles and procedures, the technology of grid formation, including some techniques required for special cell designs. Current experimental results are presented. (38 refs.)

73446 **Surface effects in high voltage silicon solar cells.** A.Meulenberg, R.A.Arndt (COMSAT Labs., Clarksburg, MD, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.348-54
The surface of low-resistivity silicon solar cells appears to be a major source of dark diffusion current. This region, consisting of the interface and the adjacent heavily doped layer, therefore, prevents attainment of the high open-circuit voltages expected from these cells. The authors describe the experimental effort carried out to reduce the varius contributions of dark current from the surface. Analysis of results from this effort points to a means of improving cell voltages by changing processing and structures. (14 refs.)

73447 **How will we get to 20% (AM1) efficient Si solar cells?.** M.Wolf (Dept. of Electrical Engng. & Sci., Philadelphia, PA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.355-60
Application of recent 'more exact modelling' methods has indicated the design principles for the achievement of silicon solar cells with efficiencies above 20% AM1. These design principles are primarily aimed at reducing the total device minority carrier recombination rate, not so much to improve the collection efficiency, but more to attain higher voltages. The reduction of recombination is attacked along three paths: increased minority carrier lifetime, reduced volume for bulk recombination, and reduced surface recombination. The lifetime control dictates the avoidance of severe Auger recombination anywhere in the device. Simultaneously, bandgap narrowing effects will also be minimised. The cells will be multilayer structures, which include high/low junctions in the base region as well as in part of the front region. The thickness of each of the layers needs to be designed in accordance to the electronic properties actually achieved in it and in the other layers. (11 refs.)

73448 **High efficiency silicon solar cells.** H.T.Weaver, R.D.Nasby (Sandia Nat. Labs., Albuquerque, NM, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.361-5
A summary of data on high-performance silicon solar cells is presented. Cells are discussed which represent state-of-the-art single crystal silicon devices and which exhibit power conversion efficiencies above 20 percent at concentration. One group of p^+-n cells exhibited open-circuit voltages (V_{oc}) as high as 0.653 V at one sun insolation. This large V_{oc} suggests that bandgap narrowing effects are smaller than has been assumed in the past for this type cell. (10 refs.)
